THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XXX.

FROM NOVEMBER 4, 1892, TO APRIL 28, 1893.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1893.

INDEX TO "THE ELECTRICIAN."

VOL. XXX.

General Alphabetical Index.

A

Aberdeen, 342, 572, (*Plans approved*) 500, 524, 581
Aberystwyth, 370. (*Prof. Garnett's Report*), 693
Abney, Capt., and Arc Light Photometry, 659
Accidents:
  Bilbao, 2
  Brighton, 409
  Brompton, 55, 58
Accrington, 146, (*Local Government Inquiry*) 532
Accumulator Patent Litigation in Belgium, 319
Accumulator Traction, 368
Acidimeter, An Electric, 470
A'COURT, S.: Gas *v.* Electricity for Illuminating Purposes, 325
Acton, 287, 752
Adams Prize, 408
Addlestone, 551
Admiralty and Departmental Inventors, 116
Aix-la-Chapelle, 471
Albert Medal, 589
Alcohol, Refractive Index of Electric Waves in, by H. O. G. Ellinger, 387
Algebra of Physics, 236
Alkali and Bleach, The Cost of, 151
Alternate Current Motors, Distribution of Power by: by Albion T. Snell, 715, 746
Alternate Current Supply, Cost of, 519
Alternate Current Transformers, Experimental Researches on: by Dr. J. A. Fleming, 97, 120, 162. *Discussion*, 193, 326, 453
Alternating Currents, Curious Attraction by: by Elihu Thomson, 603
Alternating Motor Problem, Present Position of, 388

Alternators—
  Ewing, 56, 65
  Parsons, 25, 34
  Pyke and Harris, 161
  Westinghouse, A Large, 254

Alternator and Dynamo Testing, 568
Alternators, On Testing and Working: by W. M. Mordey, 514, 545. *Discussion*, 574
Aluminium, Position of, 518
Aluminium, Soldering, 437
Amberley Road Station, 541
America, Electric Railways in, 538
American Books and the Merchandise Marks Act, 318
American Institute of Electrical Engineers, 134
American Philosophical Society, 147
American Telegraphs, 319
Ammeters, Non-Polarised, 365
Analysis of Electric Supply in London, 309
Andamans, The, Cable to, 114
Androssan, 138
Antwerp, 27, 470
Apprentices, 255
Arbroath, 287
Arc Lamps, Future of, 706
Arc Light Pillars, St. Pancras, 408, 735
Arc, Temperature of the Electric, 266, 273
Arc, Voltage of the Electric, 4
Armstrong's (Lord), Experiments, 435
ARNOLD, E.: Non-Synchronous Motor for Ordinary Alternate Currents, 444
ARNÓ, R.: Rotating Electric Field, 516
Arundel Castle, 77, 226, 257
Ashford, 50
Assessors in Technical Cases, 378
Association for the Improvement of Geometrical Teaching, 319
Association for the Protection of Telephone Subscribers 265
Aston, 20, 174
Athens, 500
ATKINSON, Ll. B. E.: Human Dynamics, 155
Atkinson's (Mr.), Presidential Address, 179
Atlantic Cables, 115
Atmospheric Electricity, 534
Atmospheric Electricity, A Collector of: by L. Palmieri, 711
Australia, The Cable Service to, 76, 210
Australian Land Lines, 236
Australian Local Authorities and Electric Lighting Enterprise, 2
Attracted Disc Experiment, Prof. Elihu Thomson's, 587
Automatic Electric Railway Signals, 295
Automatic Electric Railway Signal Company, 752
Automatic Water Gauge Stopper, 524
Ayr, 77, 727
AYRTON, W. E.: Open and Closed Magnetic Circuit Transformers, 87

B

Bacup, 489
Bagshot Park, 551
Baker-street and Waterloo Railway Bill, 599
Balfour (Mr.) on Technical Education, 250
Ballistic Galvanometer, 186
Balloons Electric Signalling from, 648
BALY, E. C. C.: Separation and Striation of Rarefied Gases under the Influence of the Electric Discharge, 444
Bandon, 20
BANDSEPT, A.: Coating of Cylinder Walls, 683
Barnard Castle, 138
Barrow, 581, 665
Barry Dock, Electric Coal Tip at, 665
Barry Island Electric Railway, 398, 470, 520, 548, 599
Batavia Exhibition, 258, 490, 524
Bath, Electric Meters at, 348, 350
Baths Lighting, 581
Bazaar Lighting, 108
Beckenham, 83, 311
Beaumont Variable Gear for Electric Traction, 564
BEDELL, —.: Law of Variation of Currents Flowing in Inductive Circuits, 5
Bedford, 349, 581, 639. (*Public Meeting*), 727
Belfast, 20, 27, 50, 77, 114, 174, 581, 693. (*Harbour Lighting*), 342. (*Fire Station Lighting*), 462. (*Prof. Kennedy's Report*), 547
Bell Ringing from Supply Circuits, 470
Bell Telephone Patent, 634
Berlin, Electric Lighting in, 148. (*Lighting Statistics*), 533
Berwick, 490
Bewdley, 266, 408
Bideford, 581, 609
Birkdale Electric Lighting Order, 588
Birkeland on Energy Movements in the Electromagnetic Field, 734
Birkenhead, 646, 665
Birmingham, 147. (*Reduction in Charges*), 665. (*Hydraulic Supply*), 647
Birmingham Tramways (*Dinner*), 342
BJERKNES, V.: On the Dissipation of the Electrical Energy of the Hertz Resonator, 69
Blackburn (*Local Government Inquiry*), 501
Blackpool, 342, 379, 551, 693. (*Tramways*), 49, 502. (*Charge for Lighting*), 581
Blackrock, 258
BLAKESLEY, T. H.: Differential Equation of Electric Flow, 653
Blake Transmitter Patent, Expiry of, 318
Blast Furnaces, Rating of, 288
Bleach, Cost of Electrolytic Alkali and, 151
BLONDEL, A.: On Oscillographs for the Investigation of Slow Electric Oscillations, 571
Blondel Arc Standard of Light, 619, 645, 658
Blondel on Electrical Units, 539
Board of Trade Electrical Standards Committee, 3, (*Report*) 152
Board of Trade Regulations with regard to High Pressure Supply, 703, 720
Bognor, 174
Boilers, "Stand by," Losses in, 348
Bolton, 138, 181, 379, 398. (*Engineer appointed*), 609
Bombay, 311, 342. (*Dockyard Lighting*), 524. (*Municipal Lighting*), 693. (*Foundation Laid*), 735. (*Market Lighting*), 752
Boot Warming by Electricity, 266
Bordeaux, 209
Boudreaux Dynamo Brush, 437
Bournemouth, 258, 462, 665, 752. (*Pier Lighting*), 524
Bovet Magnetic Adhesion Apparatus: by R. V. Picou, 508
Bowdon and Altrincham, Electric Lighting of, 2, 727
Bowness, 581, 609, 693
Bradford, 2, 437. (*Station Statistics*), 473. (*Local Government Inquiry*), 502. (*Estimates for Extension*), 705
Bradford Gas Engines, 77
Braintree, 581
Branched Circuits, Impedance of: by Alex. Russell, 299
"Bressa" Prize, 268
BREW, W.: Central Station Notes, 363
Brewers' Exhibition, 311
Bridgend, 2, 209, 227. (*Order granted*), 588
Brighton, 2, 28, 148, 294, 398, 431, 462, 561, 639, 752. (*Board of Trade Inquiry*), 380, 534. (*Report of Inspectors*), 621. (*Loan Sanctioned*), 673
Brighton Corporation Method of Charging for Electrical Supply, 407
Brighton-Rottingdean Electric Railway, 320, 399, 599, 705, 736
Brisbane, 706
Bristol, 27, 57, 138, 174, 180, 227, 431, 462, 639. (*Tenders accepted*), 398. (*Loan*), 525. (*Description of Station*), 737. (*Hospital Lighting*), 752
Bristol Lamps and Batteries, 457
British Association, 209, 532
British Museum Reading Room, 349
Brockie-Pell Arc Lamp, 20
Bromley (Kent), 138, 227, 462, 588
Brown and Hutin-Leblanc Alternate Current Motors, 505
BROWN, C. E. L.: Non-Synchronous Motor for Ordinary Alternating Currents, 358
Brown's Motor, A Hysteresis Theory of: by J. A. Kingdon, 604
Brown Non-Synchronous Motor, 437, 499
Brynmenin, 370
Brush Storage Battery Patents, 3
Brussels, 268
Buckingham, 227. (*Tender Accepted*), 582
Budapest, 311
Budapest Car, Experimental Runs with a, 387
Buoys, Electric Lighting of, 318
Bureau de Contrôle des Installations Electriques, 436, 502
Buildings, New, Preparations for running Electric Cables, 671
Burnley, 693, 727, 753
Burton-on-Trent, 77, 431. (*Inquiry*), 704. (*Loan applied for*), 727
Bury, 462
Buxton, 20, 287

C

Cable Factory in Germany, 551
Cable from Marseilles to Tunis, 408, 430
Cable Interruptions and Restorations, 3, 57, 83, 116, 147, 181, 209, 237, 267, 294, 319, 349, 379, 408, 470, 501, 533, 561, 588, 621, 646, 704, 736
Cable Rates, Australian, Indian Government, &c., 295
CABLE SHIPS—
  "Faraday," 13
  "Great Northern," 284
  "Lady Carmichael, 297
  "Mackay-Bennett," 322
  "Monarch," 183
  "Norseman," 562
  "Oersted," 85
  "Retriever, 449
  "Storenordiske," 85
  "William Hutt," 298
Cable, Proposed, to New Caledonia, 438
Cable Telegraphy, Use of a Shunt Wire with High Self-Induction in, 284
Cables, Corrosion of Lead Covered, 319
Cagliari, 525
Cairo, 287, 672
Calcutta, 736
Camberwell, 551
Cambridge, 115
Cambridge, Engineering at, 58, 389
Canal Lighting, 621
Canterbury, 236, 727
Cape Town, 288; (*Electric Lighting*), 470
Carbons: Coated, 236; Cored, 589
Cardiff, 258, 266, 294, 311, 370, 462, 582; (*Deputation to Local Government Board*), 525; (*Local Government Board Inquiry*), 590
Carlisle, 609
Carlow, 29
Carnarvon, 50
CARTER, E. T.:
  Deflection and Control of Galvanometers, 249
  Insulation Resistance of Private House Circuits, 657
  Latitude and Load Factor, 476
  Thermal Galvanometers, 680
Cathedral Lighting, 182
Cathodes, Metallic Layers obtained by the Disintegration of, by J. Mooser, 243
Cefn (South Wales), 551
CENTRAL STATIONS—
  Amberley Road, 541
  Christiana, 507
  Cologne, 519
  Mulhausen, 282
  Paris, 534
  Statistics, Large Sheet Supplement, issued on January 6th, 1893.
  Vienna, 533
Central Station Notes: by W. Brew and P. G. Ledger, 363
Central Stations, Transmission of Horse Power from, 478
Chagford, 83, 175
Charging for Current, Methods of, 114

Hosted by Google

Chatham, 138
Cheesbrough Patent, 83
Chelmsford, 693
Chelsea, 175, 227
Cheltenham, 147, 267
Chemical Laboratories, Electricity for, 383
Chemistry, Some Applications of Electricity to: by James Swinburne, 709, 745
Chester, 753
Chesterfield, 57, 582, 527
Chicago and St. Louis Electric Railway, 169, 471
CHICAGO EXHIBITION—
Elevated Railway, 648
Regulations for Awards, 560
Westinghouse Exhibit at, 471
Proposed Early Closing, 135, 210; Oil Fuel Used, 320
Proposed International Congress at, 215, 410, 390
Chiswick, 50, 202, 551, 753
Christiana, 2, 227, 507
Christmas Tree Lighting, 311
Chromium, Electrolytic Preparation of Metallic: by E. Placet, 162
Church Lighting, 342, 582, 693
City and Guilds of London Institute, 181
City and South London Railway, 147, 209, 346; (*Crowding on*), 350, 561; (*Breakdown*), 533; (*Bill*), 576
City Lighting, 37, 84, 148, 210, 227, 369, 590, 645; (*Annual Statement*), 350; (*Finance*), 490; (*Curious Short Circuit*), 577; (*Col. Heywood's Report*), 673; (*Extension*), 753
City of London Electric Light Company and the Fog, 266
City of London Electric Lighting, 369
City of London Electric Lighting Company (*Amendment of Provisional Order*), 674; (*Expenditure Diagram*), 720
City Road Windmill, 319
Clapham Junction Railway, 595
Cleckheaton, 665
CLEMENCEAU, P.:
Clamond Microphone, 309
Clock Lighting, 433
Coast Communication, 4, 84, 147, 267, 293, 589; (*Meeting*), 295, 319; (*Wreck at Ramsgate*), 380; (*Report of Royal Commission*), 396; (*Tour by the Commission*), 705
Coatbridge, 77
Coils, Choking: by J. Whitcher, 565
Coils, Finding Faults in, 83
Colchester, 20, 208, 398, 551
Commercial Cable Company, 532
Commercial Considerations at the Institution of Electrical Engineers, 179
Commercial Electrolysis, Problems of: by J. Swinburne, (*Discussion*) 69, 90
Commutators, Sparking at: by F. M. Weymouth, 160, 189, 212, 245, 323, 511, 542, 569
Companies of 1892, New Public, 280
Companies Wound up, etc., in 1892, 231

COMPANIES' MEETINGS, REPORTS, DIVIDENDS, STATUTORY RETURNS, &c.

'Abbreviations:—Mtg., Meetings of Shareholders; Rpt., Reports of Directors; Div., Dividend; Rev., Revenue; Stat., Statutory Returns.)

Abell's Electrical Engineering Company—Stat., 111
Akester Electric Syndicate 731
Allchin, Linnell and Co.—177, 405
Alwyn (L.)—Stat., 669
Aluminium Company—23; Mtg., 52; Stat., 263
African Direct Telegraph Company—233
Anglo-American Telegraph Company—Div., 345, 643; Rpt., 374; Mtg., 402; Stat., 669
Anglo-Portuguese Telephone Company—Rpt, 642
Angus (George) and Co.—Div., 315
Arcas Plating Company—315; Mtg., 617; Stat., 731
Aurora Electric Lighting and Distribution Company—Stat., 315
Automatic Electric Railway Signal Company, 529
Babcock and Willcox—Stat., 23; Div., 315
Barry and Cardiff Electric Light and Power Supply—79
Bell Telephone Company—643
Birmingham Electric Supply Company—Rpt., 528; Mtg., 583
Birmingham Telegraph Factory—669; Stat., 315; Mtg., 557
Blackpool Electric Tramway—Mtg., 669
Blakey, Emmott and Co.—529; Stat., 315
Bournemouth and District Electric Supply Company—Mtg., 697
Brazilian Submarine Telegraph Company—701; Div., 143, 557; Rpt. 757
Brighton Eiffel Tower and Winter Gardens 701
British Electrical Installation Contractors—467
British Electric Light Company—Stat., 557
Brush Electrical Engineering Co., 143; Div., 433
Cambridge Electric Supply Company—Stat., 291; Mtg., 556; Stat., 669
Carbon Electric—Stat., 291
Central and South American Telegraph Company—757
Chagford and Devon Electric Light Company—Stat., 291
Chatham, Rochester and District Electric Lighting Company—Stat., 616; Mtg., 643
Chelsea Electricity Supply Company Rpt., 497; Mtg., 527
Chloride Electrical Storage Syndicate—731
Churchill (Chas.) and Co.—Stat., 291
City of Bath Electric Lighting and Engineering Company—Mtg., 583
City of London Electric Lighting Company—53; Rpt., 668; Mtg., 695
City and South London Railway Company—Rpt., 374; Mtg., 403, 465
Collier-Marr Telephone and Electrical Manufacturing Company—Stat., 617
Commercial Cable Company—617; Div., 177; Rpt., 557
Compagnie L'Industrie Electrique d'Geneve—467
Compagnie Français du Télégraphe Sousmarins 643; Mtg., 291
Compania General Madrilena de Electricidad—643
Consolidated Telephone Construction and Maintenance Company—Mtg., 555, 643.
County of London Electric Lighting Company—Stat., 529
Crompton and Co.—Stat., 53; Div., 263.
Crompton Electrical Supply Company of Australia—Mtg., 205, 230: Stat., 345
Crossley Telephone Company—Stat., 291
Croydon Tramways Company—Mtg., 529
Crystal Palace Company—467
Crystal Palace District Electric Supply Company—Mtg., 263; Stat, 345
Cuba Submarine Telegraph Company—Mtg., 433, 493; Stat., 617
Cutting, Douglas and Co.—111
Dawson, Roger—731
Direct United States Cable Company—Rpt., 344; Div., 345, 643; Mtg., 401; Stat., 529
Direct Spanish Telegraph Company—Div., 557; Rpt., 584; Mtg., 640.
Dorman, Long and Co.—79
Douglas Patent Block and Electric Meter Company—617
Eastbourne Electric Light Company—Rpt., 668; Mtg., 697
Eastern and South African Telegraph Company—Div., 315
Eastern Extension, Australasia and China Telegraph Company—701; Mtg., 21, 729; Div., 205; Rpt., 700
Eastern Telegraph Company—23, 315, 731; Div., 205, 617; Rpt., 344; Mtg., 371, 399; Stat., 557
Edinburgh Electric Supply Corporation—143; Mtg., 262
Edison and Swan United Electric Light Company—Div., 497
Edison-Bell Phonograph Corporation—757
Edison Electric Illuminating Company—617
Edison-Gower-Bell Telephone Company of Europe—Stat., 757
Electric Clock Company—Stat., 233
Electric Construction Corporation—Rpt., 204; Mtg., 228; Stat., 405
Electric Cycle Syndicate—Stat., 233
Electric and General Contract Corporation Electricity Supply Company for Spain—Stat., 757
Electric and General Investment Company—Div., 111
Electric Lamp Company—Stat., 233
Electric Trust—Stat., 111
Electric Welding Company—Stat., 529
Electrical Advertising Syndicate—Stat., 757
Electrical Coal-Cutting Contract Corporation—Stat., 79
Electrical Company—Stat., 233
Electrical Purification Association—Stat., 757
Electrical Supplies and Fittings Company—669
Electricity Supply Corporation—263, 467; Mtg., 496; Stat., 617
Elieson Accumulator Syndicate—Stat., 757
Elmore's—53
Elmore's Patent Copper Depositing Company—Mtg., 290, 584, 698; Stat., 375
Elmore's Foreign and Colonial Patent Copper Depositing Company—Rpt., 204; Mtg., 260; Stat., 375
Elmore's French Patent Copper Depositing Company—233, 529; Mtg., 404, 614, 667, 698
Elmore's Wire Manufacturing Company—Rpt., 263; Mtg., 290, 584, 698; Stat., 375
"Energy" Gas, Electric Lighting and Power Company—79
Epstein Electric Accumulator Company—617; Stat., 529
European Sims-Edison Electrical Torpedo Company—Stat., 529
Fareham Electric Light Company—Stat., 757
Ferranti, S. Z. de—405
Foreign Electric Date and Time Stamp Company—701
Fowler Insulator Syndicate—Mtg, 205
Fowler, Lancaster and Company—617; Stat., 497; Mtg., 557
Fowler Waring Cables Company—Mtg., 259; Stat., 375
Freedman Battery Company—375
French Electrical Power Storage Company—406
Froude-Hurrell Torpedo Company—497
Galloways—Stat., 617
Georgetown Electric Lighting Company—Mtg., 205
General Electric Company—Stat., 204, 233
General Electric Power and Traction Company—Mtg., 263, 404, 465
General Hydraulic Power Company—529
Geneva Electrical Company—Div., 23
Giant's Causeway and Portrush Electric Tramway Company—Mtg., 404
Globe Telegraph and Trust Company—315; Div., 643
Gordon (J. E. H.) and Co.—467
Gordon and Fell—315
Gordon Electric Traction Syndicate—Stat., 375
Great Northern Telegraph Company—Div., 731
Gülcher (New) Electric Light and Power Company—Rpt., 233; Mtg., 289 Stat., 529
Hastings and St. Leonard's-on-Sea Electric Light Company—Mtg., 697; Stat., 757
Henley's (W. T.) Electric Light and Power Company—557
Henley's (W. T.) Telegraph Works Company—Rpt., 557; Mtg, 611; Stat., 701
Henley Telegraph and Electric Construction Company—375, 617
Herculite Manufacturing Company—315
Hobart Tramway Company—Mtg., 644, 668, 701
Holloway Electricity Company—Stat., 204
Home Telephone Company—Stat., 79
Hope and Jones Electric Organ Company—406; Stat., 669
Hornsby (R.) and Sons—Div., 111; Mtg., 178
House-to-House Electric Light Supply Company—Mtg., 535; Stat., 731
Hove Electric Lighting Company—Mtg., 111; Stat., 291
Howell, J. C.—53
Humphreys—233
India Rubber, Gutta Percha, and Telegraph Works, Company—Rpt., 433; Mtg., 464
Indo-European Telegraph Company—701; Rpt., 731
International Okonite Company—Mtg., 142, 312
Ipswich Electricity Supply Company—Stat., 23
Islington and General Electric Supply Company—Stat., 497
Italian Electrical Light and Power Company—Stat., 375
Johannesburg Lighting Company—Mtg., 667
Kennedy Storage Battery Company—Stat., 315
Kensington and Knightsbridge Electric Lighting Company—Rpt., 433; Mtg., 464, 494; Stat., 585
Keswick Electric Light Company—Rpt., 529
Kidderminster Electric Light and Power Supply—79
Kingston-upon-Hull Electric Lighting and Supply Company, 585
Lancashire and Yorkshire Electric Lighting Company—Stat., 467
Lansard Syndicate—497
Lawrence Scott and Co.—Stat., 467
Law's Electrical Appliances Company—Stat., 375
Leeds and London Electrical Engineering Company Stat., 375
Leicester Electric Light and Power Company—585
Libiola Copper Company—Mtg., 529
Lineff Electric Traction and Lighting Syndicate—Stat., 53
Lironi and Bowman—177
Lithanode and General Electric Company—Stat., 177
Liverpool Electric Supply Company—Mtg., 527; Stat., 731
Liverpool Overhead Railway Company—Mtg., 315, 465; Rpt., 433
London and Hampstead Battery Company—Stat., 53
London Carbons Manufacturing Company—177
London Electrical Tramways Company—177
London Electric Wire Company—Stat., 315
London Platino-Brazilian Telegraph Company—497 Div., 731
Maquay Syndicate—53
Mather and Platt—Stat., 23
Metropolitan Electric Supply Company—Rpt., 696; Mtg., 754
Mexican Telegraph Company—Div., 757
Mix and Genest, 701
Montevideo Telephone Company—Mtg., 22; Stat., 143
Morecambe Electric Light and Power Company—Rpt., 176; Mtg., 231; Div., 205; Stat., 345
Mountain's Wire Manufacturing Company—497, 585
Mulholland, Maugham and Co.—Stat., 467
Muntz's Metal Company—467
National Electric Supply Company—Mtg., 140; Stat., 263
National Telephone Company—143, 701; Stat., 53; Div., 177
New Australian Electric Company—669
Newcastle and District Electric Lighting Company—Mtg., 466; Stat., 585
Newcastle-on-Tyne Electric Supply Company—Mtg., 374; Stat., 467
New Shangai Electric Company—Rpt., 731
North-Eastern Telephone Company—177
Northampton Electric Light and Power Company—Mtg., 556; Stat., 669
Northern Electric Wire and Cable Manufacturing Company—Stat., 669
Nottingham Electric Light and Power Company—701
Notting Hill Electric Lighting Company—Rept., 616; Mtg., 641
Oxford Electric Company—Mtg., 262; Stat., 345
Pacific and European Telegraph Company—Stat., 143
Panulcillo Copper Company—Mtg., 205
Peru Telephone Company—Stat., 467
Petroleum Engine Company—143
Phonopore Company—Mtg., 730
Phosphor Bronze Company—Div., 467; Mtg., 557; Stat., 731
Planet Electrical Engineering Company—Stat., 701
Poole and White—467
Printing Telegraph and Construction Company of the Agence Havas—640
Pyke, Harris and Co.—701
Queen Anne's Mansions Lighting and Heating Company—264; Stat., 467
Railway Electric Reading Lamp Company—Stat., 143
Redruth Electric Supply Company—617
Reuter's Telegram Company—24, 54
Richmond (Surrey) Electric Light and Power Company—Stat., 405
River Plate Telegraph Company—143
Rockhampton Gas and Coke Company—Rpt., 585

COMPANIES (NEW ELECTRICAL, &c.) REGISTERED—

The following Companies have been Registered under the Limited Liability Acts during the past half-year:—

African Trans-Continental Telegraph Company, 263
Alkali Syndicate, 23
Alwyn, L., 143
American River Electric Power Supply Company, 584
Anderson, Taverick and Co., 204
Arcas Plating Company, 143
Ariel Company, 584
Askwith and Co., 233
Automatic Electric Railway Signal Company, 143
Automatic Gem and Gold Separator Syndicate, 263
Baily and Grundy—757
Baily, Grundy and Barrett, 405
Beatley and Gresham, 111
Birmingham Stamping Company, 528
Blaiberg and Marson, 204
Bolton (R.) and Co.—757
Bristol and Kingswood Engineering and Boiler Company, 263
British Association of Medical Electricians, 375
Burglar and Fire Alarm Company, 79
Caldwells, 643
Chesterman (J.) and Co., 263
Commelin et Cie, 528
Compagnie des Forces Electriques, 111
Compagnie Française pour l'Exploitation des Procèdes Thomson-Houston, 669
Credenda Tube Company—497
Crown Contract Company—497
Cutting, Douglass and Co., 143
Dalziel's Atlantic Telegram Company, 291
Dawson, R., 291
Domestic Telephone Company, 669
Dominion Electrical Company, 23
Drosophore Company, 177
Dynevor Spelter Company, 405
Edison Bell Phonograph Corporation, 177
Electric Anti-Corrosion Company, 584
Electric Semaphore Signal Syndicate, 584
Electrical and General Contract Company, 143
Electrical Wonder Company, 79
Electrolytic Separation Syndicate, 584
Engineering and General Contract Corporation, 204
English Electric Carbon Company, 616
Farmer (Sir James) and Sons, 143
General Metallurgical Company, 405
Gordon and Fell, 314
Heatly and Gresham, 111
Hockett, 233
Holcroft (Thos.) and Sons, 643
Holt, Thos., 584
Hopkinson (J. E.) and Co., 291
Houghton (W.) and Co.—497
Humber Lamp Company, 669
Isles, 584
Jones Patent Steel Company, 584
Keay, E. C. and J., 643
Landore Copper Company, 177
Lilly and Lilly, 528

COMPANIES, NEW ELECTRICAL, &c., REGISTERED (*continued*)—

Lister (R. A.) and Co., 584
Locke and Co., 177
London and Lancashire Electric and General Engineering Company, 528
London Mica Importers, 53
McIntyre (Jas.) and Co.—497
Mazarron Electric Light Company, 528
Measures Bros., 233
Merveilleuse Electric Arc Lamp Company—757
Metal Reduction Company, 79
Moritz, George, 467
New British Electrical Installation Contractors, 23
New Cape Central Railway, 314
New Jersey Metal Refining Works, 314
Newington, Priddle and Co., 669
North American Construction Company, 53
Oswestry Electric Lighting and Power Company, 616
Otis Elevator Company, 616
Overton, Bangor and District Gas Company, 467
Pneumatic Wheel Company—757
Pope (W.) and Son, 263
Printing Telegraph and Construction Company of the Agence Havas, 345, 616
Pyke, Harris and Co., 315
Ransome (A.) and Co., 291
Rawdon Foundry Company, 204
Revolving Advertiser Company, 315
Rollason and Slater, 467
St. Martin's Electrical Manufacturing Company, 375
Sax (Julius) and Co., 23
Scarborough Electric Supply Company, 111
Silman Bros., 467
Smyth (Jas.) and Sons, 467
Société Paul Gadot et Michel, 669
Southern Concessions Syndicate, 467
Stephens and Co., 315
Swinburne and Co—497
Tavy Iron and Engineering Works, 233
Telephone Company of Egypt—Mtg., 696
Timmins (E.), and Co., 616
Tinkers, 263
Tonks (G. T.) and Co., 528
Tucking Mill Foundry and Rockdrill Company—497
United Kingdom Economic Gas Syndicate, 177
Wallis and Stevens, 467
Walsall Electrical Company, 177
Waterhouse Electrical Manufacturing Company, 315
Weeks (W.) and Son, 53
Westminster Electric Supply Company, 643

TELEGRAMS: "INDICES," LONDON.

WHEATLEY KIRK, PRICE and GOULTY

(ESTABLISHED 1850).

ELECTRICAL AUCTIONEERS, VALUERS, AND ARBITRATORS.

49, QUEEN VICTORIA STREET, LONDON, E.C.

And Albert Square, MANCHESTER.

HOVE, SUSSEX.

TO ELECTRICAL CONTRACTORS.

WIRING, &c.

The HOVE COMMISSIONERS are prepared to receive SCHEMES, accompanied with PLANS, SPECIFICATION, and TENDER, for WIRING the Town Hall for Electric Lighting and providing Fittings and Lamps.

Plan of the Town Hall and other particulars can be obtained at the office of the undersigned upon payment of One Guinea, which will be returned upon the receipt of a bona fide Scheme and Tender.

The Commissioners reserve the right to reject all or any of the Schemes and Tenders, or to accept either of them, subject to such modification as may be thought necessary or expedient.

Schemes and Tenders, endorsed "Town Hall Electric Lighting," to be forwarded to the undersigned not later than the 18th day of NOVEMBER, 1892.

H. ENDACOTT, Town Clerk.

Town Hall, Hove, 29th October, 1892.

TO ELECTRIC LIGHTING COMPANIES and OTHERS.

The MAGISTRATES and TOWN COUNCIL of PAISLEY, in virtue of the powers conferred on them by "The Paisley Electric Lighting Order, 1891," invite TENDERS from any Company or Person for TRANSFERENCE to them of the POWERS contained in the Order.

Copies of the Order and information regarding the proposed Site for Central Lighting Station may be had on application (by appointment) to Mr. W. A. Bryson, M.I.E.E., 11, Bothwell-street, Glasgow, and Sealed Tenders, endorsed "Electric Lighting," will be received by the subscribers up till 28th NOVEMBER next.

The Council do not bind themselves to accept the highest or any offer.

YOUNG and MARTIN, Town Clerks.

Municipal Buildings,
Paisley, 27th October, 1892.

EASTERN TELEGRAPH COMPANY (Limited).

£5 PER CENT. DEBENTURES, Redeemable at Par in August, 1899.

NOTICE is Hereby Given, that the Eastern Telegraph Company (Limited) are prepared to ISSUE to the holders of the above Debentures an equal nominal amount of (Registered Perpetual) £4 PER CENT. MORTGAGE DEBENTURE STOCK in EXCHANGE.

Full particulars and the necessary forms can be had on application at the Company's Office, or at the Company's Bankers, Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, London, E.C.

The option to exchange must be exercised on or before the 15th November, 1892.

By order of the Board,
GEORGE DRAPER, Secretary.

Winchester House, 50, Old Broad-street, London, E.C.,
31st October, 1892.

THE EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (Limited).

NOTICE is Hereby Given that on MONDAY, the 14th inst., at Two o'clock p.m., at the Company's Offices, Winchester House, Old Broad-street, E.C., 328 FIVE PER CENT. FIRST MORTGAGE DEBENTURES of £100 each WILL BE DRAWN FOR PAYMENT on JANUARY 2, 1893.

Notice will be given by advertisement of the numbers of the Debentures drawn.

GEORGE DRAPER, Secretary.

Winchester House, Old Broad-street, London, E.C.

CROSBY LOCKWOOD AND SON'S NEW BOOKS.

Just published, Crown 8vo, with 350 illustrations, 12s. 6d. cloth.

THE STANDARD ELECTRICAL DICTIONARY: A Popular Dictionary of Words and Terms used in the Practice of Electric Engineering. By T. O'CONOR SLOANE, A.M., E.M., Ph.D. Author of "Arithmetic of Electricity," &c.

Ready this day, Crown 8vo, with 88 illustrations, 7s. 6d. cloth.

ELECTRIC SHIP-LIGHTING: A Handbook on the Practical Fitting and Running of Ships' Electrical Plant. For the use of Ship Owners and Builders, Marine Electricians and Sea-going Engineers-in-charge. By J. W. URQUHART, Electrician.

By the same Author.—FIFTH EDITION, REVISED, WITH ADDITIONS. Just published, Crown 8vo, with 150 illustrations, 7s. 6d. cloth.

ELECTRIC LIGHT: Its Production and Use. By JOHN W. URQUHART, Electrician.

By the same Author.—Crown 8vo, 363 pages, 113 illustrations, 7s. 6d. cloth.

DYNAMO CONSTRUCTION: A Practical Handbook for the use of Engineer-Constructors and Electricians-in-Charge. By J. W. URQUHART, Electrician.

By the same Author.—Crown 8vo, 5s. cloth.

ELECTRIC LIGHT FITTING: A Handbook for Working Electrical Engineers. By J. W. URQUHART, Electrician

Just published, SECOND EDITION, REVISED, WITH ADDITIONS, Royal 32mo oblong, 5s. leather.

THE ELECTRICAL ENGINEER'S POCKET BOOK of MODERN RULES, FORMULÆ, TABLES and DATA. By H. R. KEMPE, M.Inst.E.E., A.M.Inst.C.E., Technical Officer, Postal Telegraphs, Author of "Electrical Testing."

Crown 8vo, 420 pages, 120 illustrations, 10s. 6d. cloth.

THE ELEMENTS OF DYNAMIC ELECTRICITY AND MAGNETISM. By PHILIP ATKINSON, A.M., Ph.D.

Just published, waistcoat pocket size, 1s. 6d. leather.

TABLES, MEMORANDA, AND CALCULATED RESULTS FOR ENGINEERS. By FRANCIS SMITH. Fifth edition, revised and enlarged, with a new section of ELECTRICAL TABLES AND FORMULÆ, &c.

London: CROSBY LOCKWOOD AND SON, 7, Stationers' Hall Court, E.C.

Continued from preceding page.

WANTED IMMEDIATELY WORKING MANAGER for small High-Tension Alternating Parallel System Central Station, driven partly by steam and partly by water, in a country town. Must be experienced and practical in both Main and House Wiring.—Apply, stating age, wages, testimonials and experience to "X. Y. Z.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ELECTRICAL ENGINEER open to ENGAGEMENT; three years' practical experience in large public undertakings; first-class theoretical certificates; age 23.—"J.," care of E. Hutchings, Esq., 8, Great Queen-street, Queen Anne's Gate, Westminster.

ELECTRICAL ENGINEER desires ENGAGEMENT to take charge of installation, country residence preferred; 5½ years' practical experience. Highest references.—Apply, "A. E. B.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

EXPERIENCED ENGINEER (27) desires EMPLOYMENT in Central Lighting Station; good practical and theoretical knowledge of lighting plant; four years' experience as draughtsman with high-class engines and dynamos; two years at sea, with main engines and boilers. Would accept small salary to commence, if with good prospect.—"A. M.," 4, Lenham-road, Lee, S.E.

SITUATION WANTED by Young Man (20) who has just completed two years' course at Finsbury Technical College, and has had a year's experience in electrical engineering works. Speaks French, and is well educated.—Address, "F. W. H.," care of W. Dawson and Sons, 161, Cannon-street, London, E.C.

WANTED, EMPLOYMENT as MANAGER, Representative, or any position of trust, by Mechanical and Electrical Engineer; commercial experience; first-class references.—Apply 1,090, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

FIRST-CLASS ELECTRIC CLOCK FOR SALE (Bain's Patent), for Bracket, in perfect order, splendid timekeeper.—Address, W. COCHRANE, 24, Dixon-avenue, Crosshill, Glasgow.

NEARLY NEW "OTTO" GAS ENGINE, with 27 Accumulators for 70 Guineas.—Apply, 30, Hyde Park-gardens, W.

OLD ESTABLISHED ENGINEERING BUSINESS in YORKSHIRE FOR DISPOSAL under special circumstances. Works and Plant capable of employing 150 hands easily. Bears a high reputation for its products, chiefly heavy engineering tools for British and Foreign Governments, and most of the principal engineering firms. Although a current going concern, an exceptionally low price will be taken. Freehold Land, Buildings, Plant, and Contents under £10,000 for an immediate purchaser.—Apply to WHEATLEY KIRK, PRICE, and GOULTY, 49, Queen Victoria-street, London, E.C.

WHITTAKER'S NEW BOOKS.

By **OLIVER J. LODGE, LL.D., D.Sc., F.R.S., M.I.E.E.,** Lyon Jones Professor of Experimental Physics in the University College, Liverpool.

LIGHTNING CONDUCTORS AND LIGHTNING GUARDS. A Treatise on the Protection of Buildings, of Telegraph Instruments and Submarine Cables, and of Electric Installations generally, from Damage by Atmospheric Discharges. In one vol., with numerous illustrations, crown 8vo, 550 pp., **15s.**

"A comprehensive and most instructive treatise, which is the work of one of our best authorities on modern theories of electricity and their practical application."—*Times.*

By **W. PERREN MAYCOCK, M.I.E.E.,** Author of "A First Book of Electricity and Magnetism," &c., &c.

ELECTRIC LIGHTING AND POWER DISTRIBUTION. An Elementary Manual for Students preparing for the Ordinary Grade Examination of the City and Guilds of London Institute. Written in accordance with the New Syllabus. 125 Illustrations. Part I., **2s. 6d.,** sewed in wrapper. [*Immediately.*

By **F. C. ALLSOP,** Author of "Telephone Construction," &c., &c.

PRACTICAL ELECTRIC LIGHT FITTING. A Treatise on the Wiring and Fitting-up of Buildings deriving Current from Central Station Mains, and the Laying Down of Private Installations, including the Latest Edition of the Phœnix Fire Office Rules. With 223 Illustrations. **5s.** [*Immediately.*

By **CARL HERING.**

ELECTRIC RAILWAYS, RECENT PROGRESS IN. About 400 pages, and 120 Illustrations. Price **5s.** [*Immediately.*

By **E. J. HOUSTON, A.M.,** Professor of Natural Philosophy in the Central High School, Philadelphia; Professor of Physics in the Franklin Institute of Philadelphia; Electrician of the International Electrical Exhibition.

A DICTIONARY OF ELECTRICAL WORDS, TERMS, AND PHRASES. Second Edition. Revised, enlarged, and entirely re-written. 562 pages, 570 Illustrations. Price **21s.**

"Fills a very large gap that previously existed in electrical literature."—A. E. KENNELLY (Edison Laboratory).

"The name of the author is a sufficient guarantee of the excellence of the work."—*Electrical Review.*

"A book of this kind is absolutely necessary to the general reader who wishes to understand any modern article on applied electricity."—*New York Herald.*

By **O. T. CROSBY** and **Dr. LOUIS BELL.**

THE ELECTRIC RAILWAY IN THEORY AND PRACTICE. 400 octavo pages, 179 Illustrations. **10s. 6d.**

CONTENTS:—General Electrical Theory—Prime Movers—Motors and Car Equipment—The Line—Track, Car Houses, Snow Machines—The Station—The Efficiency of Electric Traction—Storage Battery Traction—Miscellaneous Methods of Electric Traction—High-speed Service—Commercial Considerations—Historical Notes.

APPENDICES:—Electric Railways—Telephone Decisions—Instructions to Linemen—Engineer's Log Book—Classification of Expenditures of Electric Street Railways—Concerning Lightning Protection, by Prof. Elihu Thomson.

London: WHITTAKER and CO., Paternoster Square.

"THE PATENTEES' HANDBOOK,"

BY

J. G. LORRAIN, M.Inst.E.E., M.Inst.M.E.,

CHARTERED PATENT AGENT,

Gives full information and advice to intending Patentees. Sent post free on application to Mr. J. G. LORRAIN, Norfolk House, Norfolk-street, Strand, London, W.C.

Messrs. WILLIAMS and NORGATE, Importers of Foreign Books, have weekly parcels from the Continent with all the new Scientific Books.

(*Foreign Prices*).

14, HENRIETTA STREET, COVENT GARDEN, LONDON, & 20, S. FREDERICK STREET, EDINBURGH.

MESSRS. DEBENHAM, TEWSON, FARMER, and BRIDGEWATER have a large selection of SHOWROOMS, OFFICES, WAREHOUSES, and FACTORIES suitable for ELECTRICAL ENGINEERS.

Their Monthly List is now ready, and may be obtained at their Offices, 80, CHEAPSIDE, E.C., or will be forwarded free by post

FOR ELECTRIC WORKSHOPS or EXPERIMENTS.

STEAM POWER.

ALLIANCE STEAM MILLS,

CHAPEL ROAD, STAMFORD HILL

(Close to Stoke Newington Passenger and Goods Stations, G.E.R.).

FIRST FLOOR

(nearly 3,000 square feet) or Part,

TO BE LET,

with every convenience, in these well-appointed Mills. Ample Steady Steam Power. Water and Gas all ready to start work. Benches and lathes could be arranged to suit tenant's convenience. Sanitary arrangements perfect.

RENT MODERATE.

For plans and further particulars apply by letter or personally to MANAGER, Alliance Steam Mills, Stamford Hill.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 755.—Vol. XXX. FRIDAY, NOVEMBER 4, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6.

NOTES.

The system of inviting tenders to a specification to give an appearance of impartiality, when the destination of a contract as been already settled, is, as Lord Russell complains in our Correspondence columns, a crying evil. Certain offenders are already sufficiently known to the trade, but inexperienced firms are likely to be caught by this and other tricks, which it is almost impossible to prevent. There are, however, cases in which the invitation of one or two other contractors is justifiable. A consulting engineer, for example, may be asked to draw a specification, and to give a rough idea of the probable cost, for the purpose, perhaps, of defining the extent of the work. It is altogether indefensible that before sending out the real specification he should get one or two preliminary tenders to aid him in giving a rough estimate to his client, who expects him to have this requisite knowledge. But the client may be disposed to give the order to some firm with whom he has already done business. He asks that two or three copies of the specification should be sent to leading firms, that their estimates may be used as checks. If the specification is full and clearly drawn not much harm is done, but a distinction might be made between a mere estimate and a regular tender. In the case which we have suggested it would be most unjust to invite an inspection of sites or any proceeding that would incur special expenses; and on the same grounds the preparation of elaborate plans, calculations and designs should not be demanded.

The other suggestion of Lord Russell's is reasonable. One guinea should be enough to keep off the inquisitive, but a further refinement of what sometimes amounts to a petty extortion is the sub-division of the specification into half-a-dozen or more guineas' worth. The question of the return of the guinea on receipt of a *bonâ fide* tender is outside the present subject.

The investigations which M. Ricco has made upon the relation between the passage of sunspots across the sun's disc and the magnetic disturbances which generally accompany them are rather annoying. We have an ether, we hope only one, and its duty is to transmit light and electrical oscillations, which are indeed the same thing; whether electrical disturbances travel at a different speed in a wire or a vacuum tube being another matter. The difference between various determinations of the velocity of light and of the propagation of electrical disturbances is now within the limits of experimental error; but M. Ricco, in his contribution to the Académie des Sciences, which will be found on page 8 of our present issue, suggests that something—not sunspots and not earth-currents—is propagated at the most irregular and unheard of speed of 913 kilometres per second, or 335 times slower than light. This result is arrived at by reckoning the difference in time between the passage of the principal spot across the central meridian and that of the greatest deviation of the magnetometer from the mean declination. It might most reasonably have been supposed that the intensity of any terrestrial phenomena would have been proportional to the projected area of the sunspots, or if not extending over so long a period, to the area of the nucleus. M. Ricco does not take into account the duration of the magnetic disturbance, and his communication gives no clue to any comparison between the two phenomena as a whole. Under these circumstances the apparent retardation must be accepted with caution, and in the meantime no new variety of ether or extraordinary behaviour of the present one need be postulated.

Professor Tilden calls attention in *The Times* to the abuse of scientific titles, and by this he includes both the diversity of the "letters which are supposed to indicate membership of some learned body" and the highly improper uses which are often made of them. He divides these bodies into two classes, "corporations which have been instituted and intrusted with powers for the purpose of applying a test of professional knowledge and skill, and of granting diplomas or certificates of efficiency," and "voluntary associations of men interested in the pursuit of some common subject of study, and desirous of promoting its advancement . . . more especially by the diffusion of information by means of meetings and the publications of journals or otherwise." The abuses to which he alludes are the reference to the titles of the second class "by witnesses in courts of law or candidates for public appointments as evidence of professional trustworthiness," and in testimonials or reports by public analysts.

While giving a dozen examples of each class, the letters M.I.E.E. and A.M.I.E.E. do not appear in either, and we will not venture to do what Prof. Tilden has either omitted or shirked. We are glad to hear a report that the Council of the Institution of Electrical Engineers are now exercising some care in electing its members, but a considerable time must elapse before the difference in the two orders means much more than a

Hosted by Google

difference in the subscription. Prof. TILDEN does not allude to that strange tag C.E., which any ironmonger or builder may write after his name if he likes, and it is possible that if any serious qualifications had been asked from candidates for election by the Institution of Electrical Engineers in former years, a tribe of E.E.'s or perhaps mere E.'s might have sprung up.

THE St. Pancras Vestry's central lighting station is the Mecca to which all electrically-minded Lighting Committees turn. The efficiency of conversion of that long line of Kapp-Willans sets is no doubt remarkably high, but its efficacy in convincing is equally so. No Committee's report is now complete without a preamble to the effect that, after having inspected the "installation" recently laid down by the Vestry of St. Pancras, "your Committee is of opinion that electric lighting is no longer in its infancy, but may be looked upon as having arrived at such a stage of development as to render possible its general utilisation." Within the last few days only, municipal pilgrims from places as far apart as Newport (Mon.) and Hampstead Heath have journeyed all the way to Stanhope-street to see the armatures rotate, and to revolve in their own minds the meaning of it all. Why not levy a poll-tax upon the visitors and relieve the rates?

LIVING at the Antipodes might reasonably be expected to result in Antipodeans looking at many matters from a point of view antipodal to our own. From all we hear, however, this is by no means generally the case, and, as regards the attitude of Australasian local authorities towards electric lighting enterprise, it certainly is not so. In another column we give a brief abstract of the debate which arose in the Legislative Council of New South Wales upon the second reading of an electric lighting Bill, promoted by the Australian Gaslight Company. The arguments, for and against, might just as well have been applied to Sydenham as to Sydney, for all that there was fresh or novel in them. Out in socialistic Australia the municipalities ought surely to be more vertebrate than has generally been the case in the Old Country; out there, at any rate, they should be in advance of the needs of the community, not lagging lazily behind them, and refusing to let private enterprise make up for municipal deficiencies.

New Books.—The title of Mr. Fahie's book, which will be ready shortly, has been altered to "House Lighting by Electricity."

Bridgend.—The Local Board, at a special meeting held on Friday evening, decided to obtain an Electric Lighting Provisional Order.

Liverpool Overhead Railway.—This railway is rapidly approaching completion. On Monday last the first train was placed on the metals.

International Telephonic Communication.—Steps are being taken to establish telephonic communication between Sweden and Denmark *viâ* the Sound.

Bradford.—In regard to the £30,000 voted last week by the Town Council for the extension of the Electric Lighting Works, it should be stated that it is only proposed to spend £9,000 immediately.

The Indian Telegraph Department.—The Secretary of State has sanctioned the proposal made by the Government of India regarding promotion in the Telegraph Department.

Christiania.—The machinery for the electric central station, now in course of construction, has arrived from Scotland. The work of laying down the cables is now nearly completed, and good progress is being made with the station.

A Proposed Electric Tramway in Wales.—The Directors of the Barry Railway are said to be contemplating the construction of an electric tramway from a point near the railway bridge at the East Barry end of the dock to Barry Island.

Accident.—According to a Reuter's telegram a workman at the Nervion shipbuilding yards at Bilbao was carrying some sheet iron on his shoulders, when his load came in contact with a "live" electric light wire, and the man was killed instantaneously.

Electric Lighting at Bowdon and Altrincham.—At recent meetings of these Local Boards, provisional agreements have been come to with the Manchester Swan-Edison Company for the lighting of the whole district of Bowdon and Altrincham.

Phosphorescent Zinc Sulphide.—Professor C. Henry has recently drawn the attention of the members of the Académie des Sciences to the phosphorescent character of zinc sulphide obtained from the sulphate, and suggests its use as a standard for photometric work.

The Johnstone Conduit.—The City of London Electric Light Company are going to lay down some "Johnstone" conduits (which are owned by the International Electric Subway Company), for telephone cables. The work will shortly be commenced in John Carpenter-street, Blackfriars.

The Western Union Telegraph Company.—The *Electrical Review* of New York states that it is in possession of information which leads it to believe that the negotiations for the absorption of the Postal Telegraph Cable Company by the Western Union Telegraph Company are nearly completed.

Leeds.—The Board of Trade have given their formal approval of the system adopted by the Yorkshire House-to-House Electricity Company. The Company are said to be meeting with good demand for the light. Every effort is being made to be ready for commencing the supply of current by December 1st.

The Accident to the Scotch Express.—The Marquis of Tweeddale was amongst the passengers by this train who escaped unhurt, and he was received with cheers and warmly congratulated, on making his appearance at the meeting of the Eastern Extension, Australasia and China Telegraph Company, of which he is a Director, at Winchester House, on Wednesday afternoon.

Leicester.—At the last meeting of the Town Council, Alderman Lennard said that the Gas Committee had expected to have been in a position to bring the electric lighting question forward. Tenders from 13 firms had been received, but they had found on going into them that they were all technical in character and required much examination and careful dealing with.

Hull.—The Town Council having applied to the Local Government Board for power to borrow £25,000 for laying down a system of electric light, Major-General H. D. Crozier, R.E., held an inquiry into the matter last week. The proceedings were only formal, there being no opposition. The details of the scheme were laid before the Inspector, who afterwards visited the lighting station.

Brighton.—At the meeting of the Town Council on Monday it was decided to largely extend the area of supply of the Municipal central station. The Lighting Committee stated that 10,248 8 c.p. lamps were now connected to the mains, and that last week the station made a net profit of £70. The loss on the first three months' (October—December, 1891) working was £280, and that on the first six months of the present year was about £650.

A Telegraph Strike.—The strike of telegraphists on the Atchison Company's system was due, it is said, to a young tele-

Hosted by Google

graph operator, who, in a playful mood, thought he would alarm the managers by sending a despatch in the name of the chief of the Telegraphists' Union ordering the men to come out. They came, and, what is more, 500 of them were so hurt on finding they had been hoaxed that they resolved to continue the strike as a protest against things in general.

Personal.—Sir James N. Douglass is, in consequence of ill-health, about to retire from the post of Engineer-in-Chief to the Trinity House. The Elder Brethren have appointed Mr. Thomas Matthews as their Engineer.——Mr. Howard Tasker, who has been chief electrician to the Chelsea Electricity Supply Company for some years, has recently severed his connection with that Company. On the occasion of his departure he was presented with a suitable *souvenir* by the *employés*.

Glasgow Physical Society.—Among the Papers down for reading before this Society during the Session 1892-3 are the following:—December 16th, "The Thermo-electric Power of Platinum and Mercury," by Angus M'Lean, B.Sc.; January 27th, "Portative Electric Energy," by J. T. Niblett; February 10th, "Further Notes from the Board of Trade Laboratory," by J. Rennie; April 14th, "Capacity and Insulation Tests," by A. W. Meikle, M.A.; April 28th, "Electrical Engineering Laboratories," by J. D. Cormack, B.Sc.

Physical Society.—At the meeting of this Society last week, the discussion on Mr. Williams's Paper "On the Relation of Physical Quantities to Directions in Space," was opened by Prof. Perry, who read a communication from Prof. Fitzgerald. Mr. Madden, Prof. Rücker, Prof. Henrici, and Dr. Sumpner followed, and the discussion was adjourned. We hold over our report until we can give the complete discussion. Papers on "Molecular Physics" were taken at this meeting, and the discussion of these was also adjourned.

Cable Interruptions and Restorations:—

	Interrupted.	Restored.
Hong Kong Foochow	Oct. 22, 1892	Nov. 1, 1892.

Telegrams for Shanghai, Amoy, Foochow and Japan can now be sent "*viâ* Eastern."

Cables actually interrupted.	Date of interruption.
Bissao-Bolama (communication with)	September 8, 1892.
Cayenne-Vizeu.....	September 24, 1892.
Jamaica-Colon	October 13, 1892.
Para-Maranham	October 15, 1892.
Hong Kong-Amoy	October 22, 1892.

The Brush Storage Battery Patents.—On the 4th ult. the United States Circuit Court of Appeal gave judgment in the suit of Brush Electric Company *v.* Electrical Accumulator Company, sustaining on a somewhat narrower basis the original judgment of Judge Coxe, given in the Circuit Court on July 23, 1891, upholding Brush's claims covering the pasted plate. As an American contemporary rightly remarks, "This litigation has been the principal business engaged in by the manufacturers of storage batteries for a number of years, and it has naturally resu'ted in very little progress in the improvement of the cells."

Montreal.—The Montreal Street Railway Company, to whom, as was stated in our issue of September 16, p. 528, the exclusive privilege of working the tramway system of that city by electricity has been conceded for 30 years, have since August 1st been energetically pushing forward the work, and successfully inaugurated electric traction on Sept. 21st by the opening of a line of four miles of single track, extending from the centre of the city to the exhibition grounds. In addition, one of the old lines, consisting of four miles of double track, was equipped and in operation some ten days later. For present use the Company has 20 motor cars of American manufacture and 15 of Canadian make. Between 80 and 100 cars will ultimately be wanted.

Board of Trade Electrical Standards Committee.—At a meeting of this Committee, held on Thursday the 27th ult., the report made to the British Association by the Electrical Standards Committee of the Association in August last was discussed, and the supplementary report which the Committee propose to make to the Board of Trade was considered. The following members were present:—Sir Courtenay Boyle, Major Cardew, Mr. W. H. Preece, Lord Kelvin, Lord Rayleigh, Prof. Carey Foster, Mr. R. T. Glazebrook, Dr. John Hopkinson, Prof. W. E. Ayrton. The supplementary report is now being drafted, and a final decision will shortly be arrived at.

The Lighting of the Corporation Central Markets.—This afternoon the Lady Mayoress will inaugurate the electric light which is being supplied at the Central Markets by Messrs. Julius Sax. Some 300 16 c.p. lights are already fixed, together with 50 50 c.p. lights in the central avenue supplied by Messrs. Sax to the Corporation free of cost. A temporary plant has been laid down close to Farringdon-street Station consisting of a 50 H.P. Davey Paxman locomotive boiler and horizontal engine driving an Elwell-Parker dynamo supplying 200 amperes at 100 volts. We are informed that orders have been received for 8,000 lights varying from 16 to 50 c.p., and it is intended to lay down 6 200 H.P. direct-coupled steam dynamos.

The Phonopore.—Mr. Langdon-Davies informs us that his Phonopore patents have become the property of the Phonopore Syndicate, which has recently been converted into the Phonopore Company, and that his contract (which was for technical services only) has now terminated, his personal connection with the Company having ceased on September 30th last. Mr. C. E. Spagnoletti, as we have previously announced, is now Managing Director of the Phonopore Company. Communications on the subject of the Phonopore should be addressed either to Mr. Spagnoletti, or to the Secretary, the Phonopore Company, Faraday House, Charing Cross-road. Mr. Davies now proposes to occupy himself with the development of his Rapid Submarine Telegraph and new Telephone Apparatus, &c. All correspondents should address: Mr. Davies, 45, Redcliffe-square, S.W.

The Electric Light and Insects.—Mr. D. S. Stewart records in a recent number of the *Entomologist* that at the Eddystone lighthouse exhibited in the Botanic Gardens at Old Trafford (the same lighthouse as was shown at the Naval Exhibition), he saw one evening in August great numbers of moths. Before ascending, he says, one could see them from below, flashing in and out of the rays in hundreds; and when the top was reached the place was found to be full of them—"some, apparently dazzled by the light, frantically flying in all directions, buzzing and banging in your face, up your sleeves, down your neck, everywhere. In every sheltered niche and cranny four or five were to be seen together, and especially was this so on the staircase, which was strewn with their partially cremated remains, the result of their all too successful attempts at self-immolation."

Hertzian Oscillations.—In his treatise, "On the Propagation of Electric Force," Prof. Hertz mentions some experiments tending to prove that the production of resonance and the period of oscillation in resonators are not influenced by the specific resistance or the magnetic properties of the secondary conductor. But if the phenomena be observed electrometrically, the individual properties of the metals soon show themselves. This method has been employed by V. Bjerknes, who gives an account of his results in *Wiedemann's Annalen*. Experiments made with copper, brass, German silver, platinum, nickel, and iron show that metals have different powers of absorbing the energy of electric waves. The rate of absorption increases with the resistance and with magnetisibility of the metal. Iron and nickel were able to follow the oscillations to a certain extent, which means that their magnetisation was actually reversed one hundred million times per second.

The McEvoy Night Sight for Heavy Guns.—This form of night sight has now been adopted nearly all the world over. The foresight consists of a socket which fits on to the ordinary day sight, and which carries a small electric lamp inside it. The light given by the lamp illuminates a small glass cone which forms the tip of the fore sight. The rear sight is constructed on the same principle, but the electric lamp illuminates a wire placed above it; this wire forming the cross of the "H" invariably used by the navy for the rear sight. In order to distinguish the rear sight from the fore sight, a red light is used with the former; this colour can be produced either by colouring the small electric lamp, or by painting the cross wire with red enamel. The current for illuminating the lamps is usually provided by a three-cell Leclanché battery,

Hosted by Google

but the employment of a small dynamo for the illumination of the night sights, as well as for firing the guns, is under consideration.

The Use of the Search Light in Military Operations.—On Saturday evening last the 4th Middlesex R.V. carried out some interesting night operations near Ealing, with a view of testing the general utility of the search light, The light, which was manœuvred by Capt. Ronald Scott, was mounted on an ordinary waggon containing a battery of accumulators from which the necessary current was derived. Owing to non-completion of the specially designed carriage now in course of construction having broad tires to prevent the wheels from sinking into soft ground, and the extremely sodden state of the soil, it was not feasible to take up the position originally intended. The object of the attack was Horsenden Bridge. The attacking column was discovered half-a-mile from the bridge. In the course of the evening advertisements were thrown on the clouds by means of a projector. We understand from the *Daily Telegraph* that Mr. Scott claims to be the inventor of this mode of advertising.

Coast Communication.—In consequence of the difficulty of connecting Rathlin Island, off the north coast of Ireland, by telegraphic cable with the mainland, the committee of Lloyd's have been making trial of carrier pigeons. So far this experiment has proved very successful. During the naval manœuvres 33 pigeons were placed at the disposal of Captain Henderson, of Her Majesty's ship "Arethusa." Of the 33 birds only eight were trained, and these had been trained only to fly from Rathlin Island to the mainland, a distance of nine miles. The remainder were young birds and untrained. Captain Henderson reports that 17 birds were flown with messages when the ship was cruising near the Mull of Cantyre and Rathlin, the eight trained birds and nine others. The eight homed safely at Ballycastle, also three of the untrained birds. Captain Henderson judges from these results that well-trained birds may be trusted to convey messages from squadrons and ships for distances extending several hundred miles from the land, and may be the means of saving much wear and tear of ships and consumption of coal.

Manchester.—The bulk of the engine and boiler plant for the Municipal Central Station is being built by Messrs. J. Galloway and Sons, who are putting down six large boilers to work at 125lb. pressure, and four compound engines, each of 400 H.P.; whilst Messrs. Hornsby are supplying six smaller engines of 100 H.P. A couple of Green's economisers, containing an aggregate of about 600 pipes, are also being put down, and the boilers will be fitted with Vickers's mechanical stokers. The whole of the steam and feed pipes, which will be of wrought iron, are being supplied by Messrs. Galloway, and are to be put down in duplicate throughout. The dynamos are being partly constructed by Messrs. Mather and Platt, and partly by the Electric Construction Corporation, whilst the mains are being put down by the Okonite Company. The Corporation are also laying down a system for the supply of hydraulic power. The hydraulic power will be distributed through pipes, ranging from 3in. up to 7in. diameter. The pressure will be at 1,200lb. to the square inch. The power used will be charged for through meters, and a special feature of these, says *The Engineer*, will be that the measurement will be taken off at the exhaust instead of the supply.

The Voltage of the Arc.—In a recent number of the *Electrical World* Mr. J. R. Cravath writes as follows:—"In a former article (see *The Electrician*, Vol. XXVIII., p. 568) I gave the results of some experiments on the hissing of the electric arc. I did not then attempt to explain the fall of voltage in the hissing arc. I gave reasons for supposing that the hissing was due to the sudden heating of comparatively cool carbon to the boiling point. It has occurred to me since that this same cause might be made to account for the fall of voltage in the transition from the normal to the hissing arc. May it not be that the constant change in position of the positive evaporating surface and the constant heating of cool carbon to high temperature has in some way a 'dampening' effect, and so prevents the consumption of energy, and causes a drop in the voltage at the point where hissing begins? At least the crater is the centre of energy. Messrs. Cross and Shepard, in a Paper before the American Academy in 1886, showed that the cooling of the positive carbon resulted in a great fall of potential and great hissing and unsteadiness. This would seem to point in the same way. This is only advanced as a suggestion based on the facts as they seem at present, and future research may prove it wrong. The writer has himself had no opportunity to investigate the matter properly."

Electric Lighting in New South Wales.—Upon moving the second reading of the Australian Gaslight Company Electric Lighting and Supply Bill recently in the Legislative Council of New South Wales, the mover said that this was an instance in which private enterprise was anxious to do something which would take up a section of the surplus labour. In this Bill it was not proposed to absolutely part with the rights of the Municipalities. The Bill only contemplated giving the Company the power to take up the work if the different Municipalities interested agreed to permit it. There was nothing of a monopoly in the measure. There was nothing to prevent any other Company or a Municipality supplying electricity if they so desired. The maximum amount to be charged was 1s. per unit. (Gas in Sydney is 5s. 3d. per thousand.) The opponents of the measure said it was not only inadvisable but positively dangerous. The Company would under it have the right to run overhead wires conveying a current up to 3,000 volts pressure, while it had been proved that a current of 400 volts was deadly. Supposing this Bill were passed, the Company would "peck the eyes" out of the city, and would extend its wires to the most thickly-populated parts of it, while the more sparsely-peopled portions would be left unserved. Moreover, most electricians admitted that they were only now beginning to find out how ignorant they were, and it was expected that great advances would almost immediately be made in electric lighting. The proper body to supply electricity was the Local Authority. It would be in the interests of the people of Sydney that the Bill should be rejected, and the matter left over for a year or two, to see what the Council would do. The motion for second reading was defeated by 77 votes to 7.

Physiological Experiments with Magnets.—At the recent (second) annual meeting of the American Electro-Therapeutical Association in New York, Dr. F. Peterson and Mr. A. E. Kennelly described experiments made by them with magnets of great power at the Edison laboratory. The pole-faces of the magnet were 1·2cm. apart, and between these poles objects were placed for observation. The intensity of the field was about 5,000 lines per sq. cm. Experiments were made on blood, which was found to be unaffected in any way. Experiments upon frogs failed to give any result. Then the effect of a continuous current was noted, and circulation was found to cease. Benedikt's statement that magnetism will produce paralysis was then tested. A set of idle field magnets converging into a cylinder two feet in diameter and seven inches deep was employed. In this cylinder a dog was placed for five hours without the slightest visible effect. Experiments were next tried upon the brain. The armature and one journal were removed from a dynamo converting about 70 H.P. at full load, and in the space between the pole-pieces the subject placed his head. The intensity of the magnetic field produced was about 2,500 C.-G.-S. lines per square cm. A switch was arranged to open and close the exciting circuit. Sphygmographic tracings, taken continuously, showed no change in regularity. The respirations were not changed in the least, and there were no sensations that could be attributed to magnetic influence. Experiments in connection with reversed magnetism also failed to show any effect upon the subject. From these experiments the authors conclude that the human organism is unaffected by the most powerful magnets known to modern science; that neither direct nor reversed magnetism exerts any perceptible influence upon the iron in the blood, upon the circulation, upon ciliary or protoplasmic movement, upon sensory or motor nerves, or upon the brain. It may be remembered that Mr. Kapp and others have placed their heads in the space which is, as a rule, more usefully occupied by the armature of a dynamo, without experiencing any sensation whatever. In these cases, the magnetic flux was no doubt shunted to a great extent by the horns of the pole-pieces.

THE LAW OF VARIATION OF CURRENTS FLOWING IN INDUCTIVE CIRCUITS.

In a lengthy Paper presented last June to the American Institute of Electrical Engineers, Messrs. Bedell and Crehore discuss the general solution for the current flowing in a circuit containing resistance, self-induction, and capacity, in consequence of any impressed electromotive force. The Paper contains no fewer than 204 equations with the accompanying proofs, and occupies 70 pages of print; but the feature which is of most interest and importance arises from the fact that a number of curves have been drawn to illustrate the equations and to show how the currents, &c., vary in certain numerical cases. These curves are more convincing and are easier apprehended than the mathematics, and a reproduction of them will prove instructive.

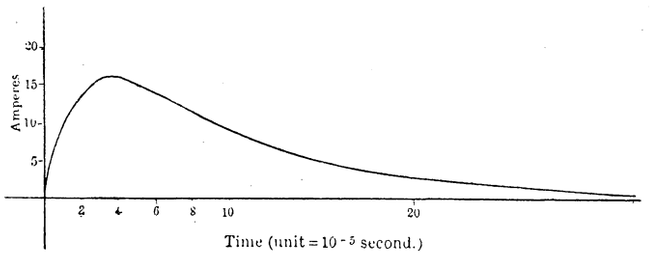

FIG. 1.—Curve showing current during non-oscillatory discharge of condenser with capacity C=1 micro-farad, through a circuit with resistance R=100 ohms, and self-induction L='0016 henrys, when originally charged to a potential of 2,000 volts.

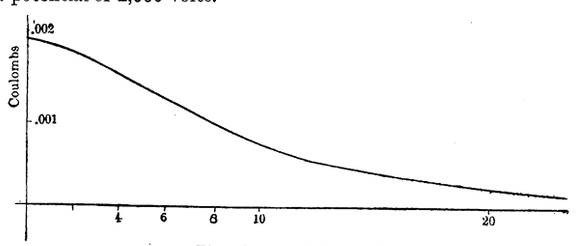

FIG. 2.—Curve showing non-oscillatory discharge of a condenser with capacity C=1 micro-farad, through a circuit with resistance R=100 ohms, and self-induction L='00016 henrys, when originally charged to a potential of 2,000 volts.

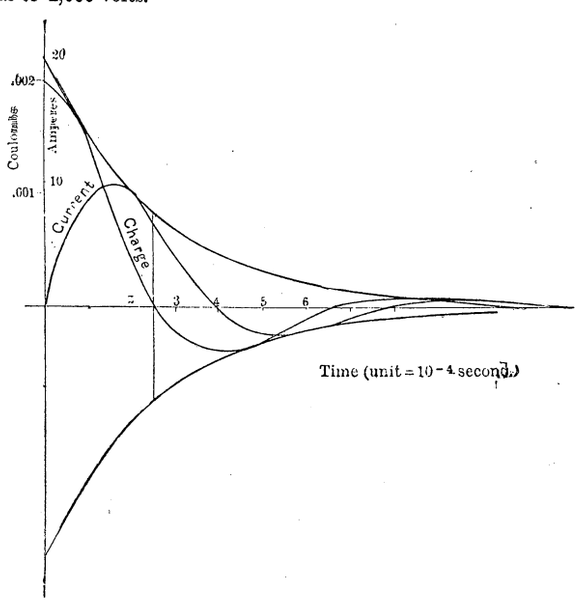

FIG. 3.—Oscillatory discharge of a condenser with capacity C=1 micro-farad, through a circuit with resistance R=100 ohms, and self-induction L='0125 henrys, when originally charged to a potential of 2,000 volts.

As is well known, the discharge of a condenser is continuous or oscillatory according as the capacity exceeds or falls short of a certain limiting value dependent on the self-induction and resistance of the circuit. Figs. 1 and 2 represent respectively the current flowing in the circuit, and the charge existing in the condenser at various times during the discharge of a condenser in a circuit for which the discharge is non-oscillatory, and the two curves in Fig. 3 represent the same quantities when the discharge becomes oscillatory. In the limiting case when the discharge is just non-oscillatory, Fig. 4 represents what happens. If the condenser, instead of being discharged, is

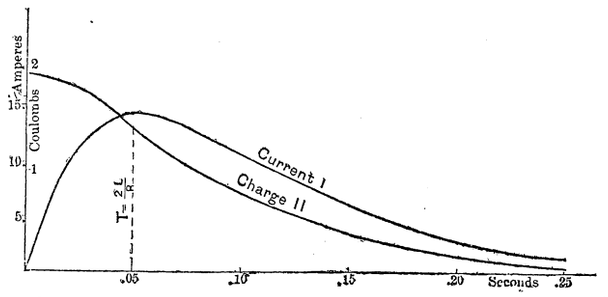

FIG. 4.—Just non-oscillatory discharge of a condenser with capacity C=1,000 micro-farads, through a circuit with resistance R=100 ohms, and self-induction L=2·5 henrys.

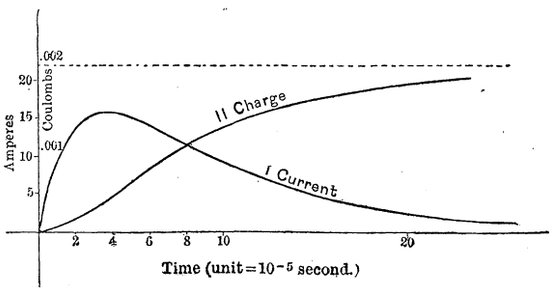

FIG. 5.—Non-oscillatory charge of a condenser with capacity C=1 micro-farad, through a circuit with resistance R=100 ohms, and self-induction L='0125 henrys when subjected to a potential of 2,000 volts.

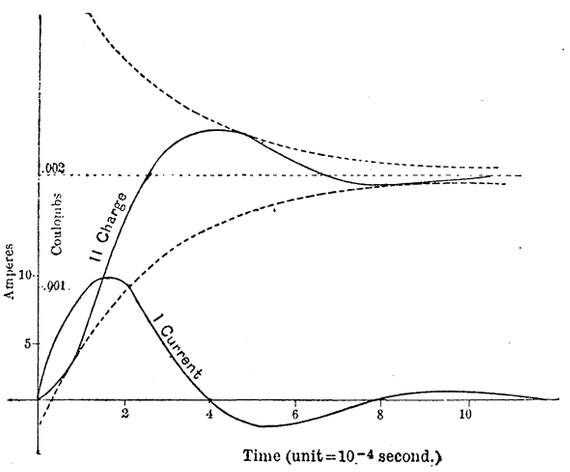

FIG. 6.—Oscillatory charge of a condenser with capacity C=1 micro-farad, through a circuit with resistance R=100 ohms, and self-induction L='0125 henrys, when subjected to a potential of 2,000 volts.

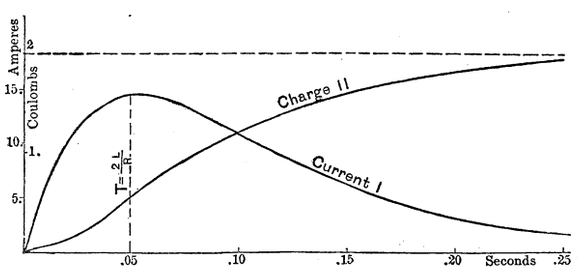

FIG. 7.—Just non-oscillatory charge of a condenser with capacity C=1,000 micro-farads, through a circuit with resistance R=100 ohms, and self-induction L=2·5 henrys.

charged by making contact with the external circuit, the curves are similar in character and are represented, for the three corresponding cases, in Figs. 5, 6, and 7 respectively.

When an alternating electromotive force of E volts acts in a circuit of resistance R ohms, having a self-induction of L.

Hosted by Google

henrys, the circuit being completed through a condenser of capacity C farads, the current in amperes which results is

$$\frac{E}{\sqrt{R^2+\left(L\omega-\frac{1}{C\omega}\right)^2}}$$

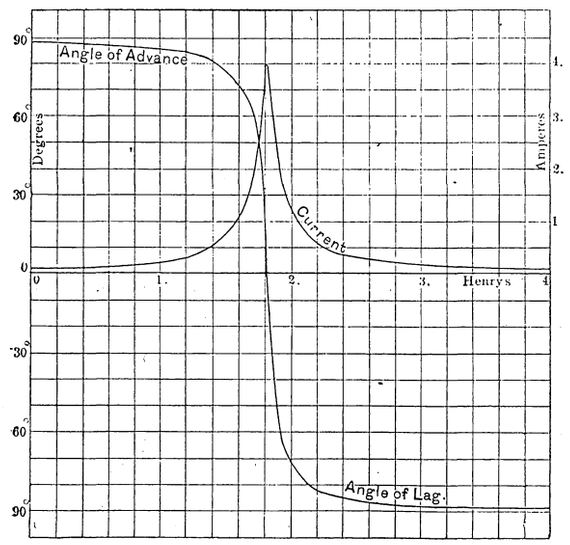

FIG. 8.—Value of current, and angle of advance or lag for different amounts of self-induction in a circuit in which R=50, C=55, E=200, ω=1,000.

constant, and the other varied there will be a particular value of this third quantity for which the current will attain a maximum value and at which the current will coincide in phase with the electromotive force E. The curves shown in Figs. 8, 9, and 10 illustrate these facts very clearly. In Fig. 8 the self-induction L is supposed to vary, in Fig. 9 C

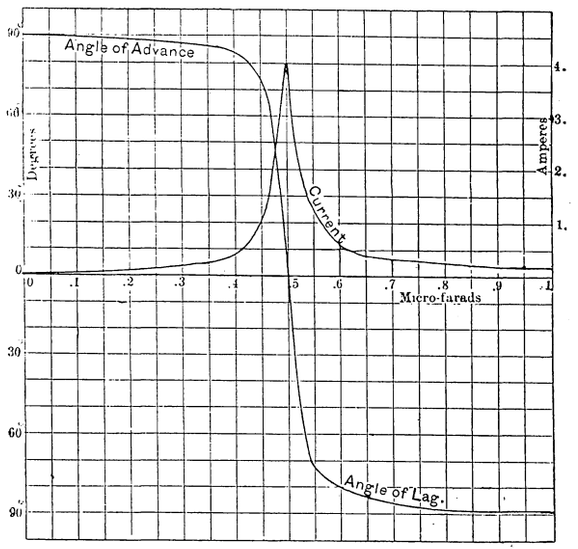

FIG. 9.—Value of current, and angle of advance or lag for different capacities in a circuit in which R=50, L=2, E=200, ω=1,000.

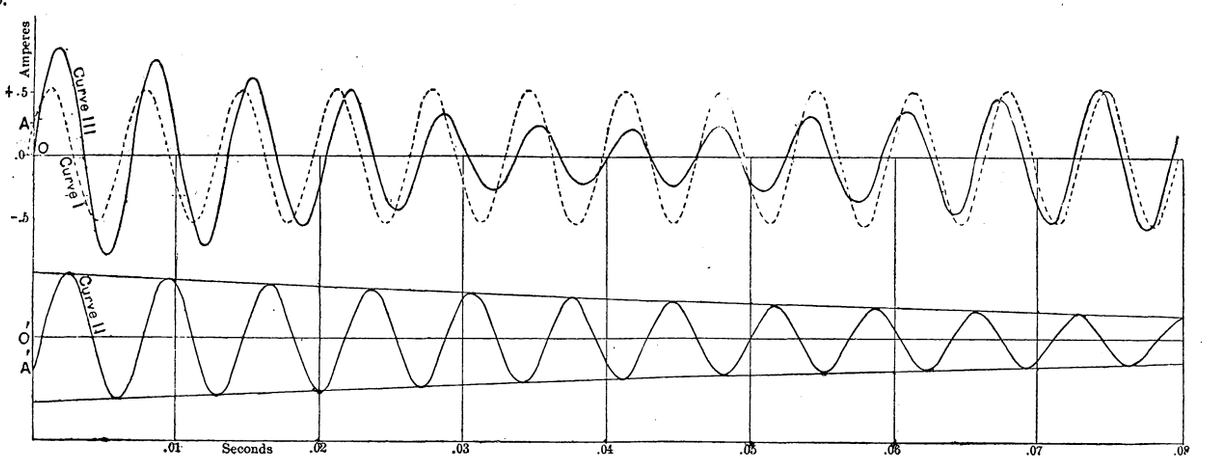

FIG. 11.— Curve III. shows the current which flows after the introduction of a harmonic electromotive force into a circuit with R, L, and C. It is the sum of the two component curves, 1, a sine-curve, and 2, a sine-curve with an amplitude decreasing according to a logarithmic decrement.

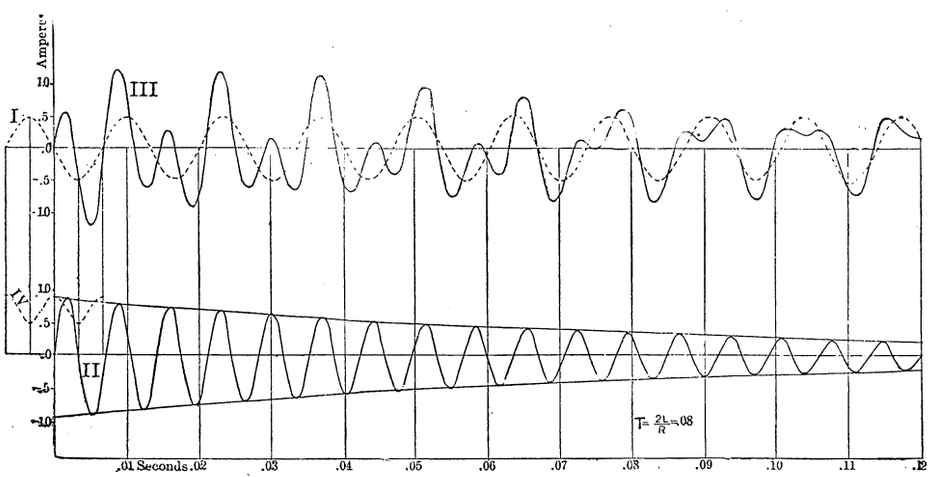

FIG. 12.—Curve III. shows the current which flows after the introduction of harmonic electromotive force into a circuit with R, L, and C. It is the sum of the two component curves, 1, a sine-curve, and 2, a sine-curve with an amplitude decreasing according to a logarithmic decrement.

where $\omega = 2\pi n$ and n is the frequency in periods per second. The phase of the current is in advance, or lags behind, the electromotive force E according as $1/C\omega$ is greater or less than $L\omega$. Accordingly if two of the quantities L, C, ω be kept

is altered, and in Fig. 10 it is the frequency which is supposed to change.

The curves in Figs. 8, 9, and 10 illustrate what is known as the periodic state, that is the state of things which obtains

Hosted by Google

some time after the application of the periodic electromotive force E, and when the variations of the current strictly follow those of E. For the first few moments after applying E the currents do not assume their final form, and the current at any moment may be described as being the sum of two currents, one being the periodic current and the other an extra current which rapidly dies away. These component currents are

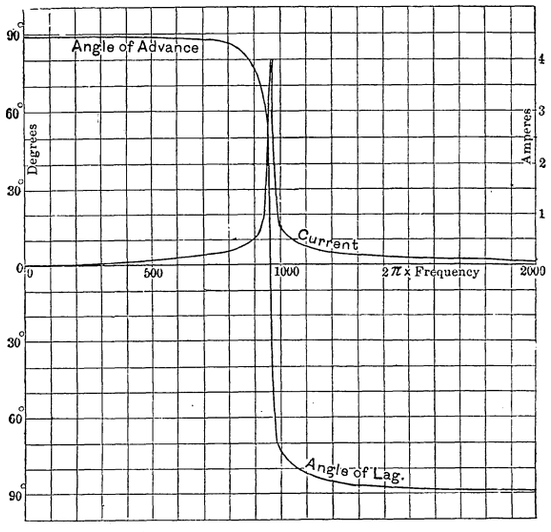

FIG. 10.—Value of current and angle of advance or lag for different frequencies in a circuit in which R=50, L=2, C=·55, E=200.

represented in Figs. 11 and 12 by curves I. and II. the resultant current is shown in the same figures by curve III., and the manner in which it is modified till it gradually assumes the periodic form shown in curve I. is clearly shown in the particular cases considered.

THE HOPKINSON THREE-WIRE PATENT.

The following is an abstract of Specification No. 3,576* of 1882, which was filed in its final form by Dr. John Hopkinson in the Patent Office on January 27, 1883. The title *after* amendment on June 22, 1891, is "Improvements in Distributing Electricity, and in Apparatus to be Employed for that Purpose." The title *before* amendment was as follows:—"Improvements in Distributing and Measuring Electricity and in Apparatus to be Employed for those Purposes":—

My improvements principally relate to maintaining the electromotive force in a system of conductors for an electric supply at a fixed potential, but they also relate to reducing the cost of such conductors consistently with efficiency and safety. When electricity is delivered by means of a pair of conductors to a distance from the station where the electricity is generated, there is a fall of potential due to the resistance of such conductors greater as the current is greater, and if it be desired to maintain the potential constant at the delivery end, it is necessary to increase the potential at the supply end, as the current increases, in a suitable manner. To ascertain the potential at the far end of the conductor, I make use of a galvanometer differentially wound with two coils, the one coil having a high resistance as for measuring potential and the other coil, of very low resistance, conveys the current to the main conductor, and acts in opposition to the high resistance coil. The differential coils may be wound on an electro magnet which acts as a relay to ring an electric bell, or to set in motion or reverse a small dynamo machine to adjust resistance or control the speed of the steam engine for the purpose of keeping the potential on service main conductors constant. An approximation to the same end may be attained by winding on the electro-magnets of the dynamo machines in addition to the usual coils, whether in shunt or conveying a current from a separate exciter, a few coils conveying the current to the main conductor, the effect of such coils being suitably adjusted. For the purpose of economising the cost of main conductors I place two dynamo machines in series, and I place two systems of lamps or other appliances consuming electricity of approximately equal capacity also in series. A main conductor is taken from each extreme pole of the two dynamos, and a smaller conductor from between the two dynamos to points between the two systems of lamps, this intermediate conductor serving to bring back to the central station any electricity required for one system of lamps in excess of that required for the other system of lamps. The iron casing used to protect the two main conductors may be used as intermediate conductors. More than two dynamos may be placed in series, and more than one intermediate smaller conductor may be used on the same principle as is above described.

Eleven lines relating to improvements in meters and switches are struck out. Up to this point the final specification is identical with the provisional:—

And in order that my said invention may be fully understood I shall now proceed more particularly to describe the same, and for that purpose shall refer to the several figures on the annexed sheets of drawings. Many devices have been proposed and used for keeping the difference of potential between the terminals of dynamo machines constant or for indicating when such potential deviates from its standard amount. When the electricity is to be used at a distance from the dynamo, and conductors of a sensible resistance are used, it is proper to maintain constant the difference of potential at the end of such conductors where the electricity is used, and not at the dynamo itself. If e be the difference of potential of the poles of the dynamo r, the resistance of the conductors from the dynamo to the place where the electricity is to be used, and c the current, it is necessary to maintain not e constant but $e—r\ c$, which is equal to the difference of potential of the two conductors at their other end.

Here follows a description of a differentially-wound galvanometer:—

This may be arranged either to indicate directly to the eye when the value of $e—r\ c$ is incorrect, or it may be used to operate as a relay and by making an electrical contact may cause a bell to ring or it may operate to introduce resistance or take resistance from one of the dynamo circuits, or it may be used to control the speed of the engine by any suitable method which has been proposed or used for maintaining the difference of potential constant between the poles of a dynamo machine. Fig. 2 shows how the differential instrument may be arranged to act as a relay. The application of this instrument to an extended system of electrical supply with a network of distributing mains is important. For each machine I provide a pair of feeders of a size appropriate to the current they are to carry, but independent of the distance they have to go. Each pair of feeders goes to

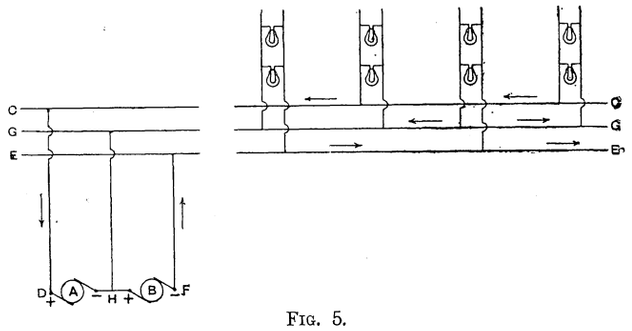

FIG. 5.

and is connected to some part or other of the system of distributing mains, and by the use of my invention I am able to keep the difference of potential constant at or near the point where the feeders join the distributing mains. By using a sufficient number of feeders I am able to keep the potential throughout the distributing mains very nearly constant; however, the distribution of the consumption may vary without requiring conductors of excessive size.

Here follows a description of a method of winding the magnets of a dynamo with shunt and main coils:—

I make no distinct and separate claim for the doubly-wound magnets above described, but have explained them here because they may be usefully employed, with a slight modification, in combination with the conductors as arranged under the next described head of my invention, and also in combination with the first described head of my invention.

In order to combine the advantages of comparatively high potential in the feeding conductors with lower potential in the houses in which the electricity is used, I make use of a system of three conductors in combination with two dynamo machines coupled in series. This system is shown diagrammatically in Fig. 5, where A B represents the two dynamos, C D and E F represent the extreme conductors which I will call the positive and negative conductors, and G H represents the intermediate conductor. The positive pole of the dynamo machine A is connected to the conductor C D, and its negative pole to the conductor G H. On the other hand, the positive pole of the dynamo machine B is connected to the conductor G H, and its negative pole to the conductor E F. The houses to be supplied are divided into two approximately equal parts, preferably the houses being taken alternately. The houses of one part are supplied between the conductor C D and the conductor G H, and those of the other part between the conductor G H and the conductor E F. The intermediate conductor G H may be of much smaller dimensions than either of the other two, as it has only to carry the difference of current consumed by the two divisions of consumers, that is those connected with the conductor C D and those connected with the conductor E F. It need not be insulated, and indeed it may be replaced by the iron or other metallic covering often used to protect the copper conductors. In cases where the two divisions of consumers may be safely assumed to have a very approximately equal consumption at all times, the intermediate conductor G H may be replaced in part by the earth and the negative pole of

Hosted by Google

the dynamo machine A, and the positive pole of the dynamo machine B be connected together and to the earth.

This system may be extended by using more than two dynamos in series and dividing the consumers into as many groups, there will then be two large conductors connected to the extreme pole of the dynamos, and a number of smaller intermediate conductors, one less than the number of machines, each connected to the junction of two machines of the series.

To apply the indicating or regulating apparatus of the hereinbefore first described head of my invention to the system of conductors hereinbefore last described, it is necessary to wind a third coil to convey the current going or returning by the intermediate conductor G H; it is, in fact, necessary to maintain $e - r_1 c_1 - r_2 c_2$ constant, when e is the difference of potential between the pole of the dynamo machine; r_1 is the resistance of the conductor C D, r_2 is the resistance of the conductor G H, and c_1 c_2 are the currents in these conductors.

In like manner, to apply the approximate method above described to the system of these conductors two main circuit coils are required on the dynamo machine, but the method of adjustment is the same as in the simple case.

Some 44 lines relating to improvements in meters and switches are here struck out.

The foregoing description of instruments relates more particularly to continuous currents, but it is obvious that the arrangements are also applicable to alternate currents, but in that case the iron in the electro-magnetic apparatus must be so divided that local induced currents are prevented.

Having now described and particularly ascertained the nature of my said invention, and the manner in which the same is or may be used or carried into effect, I would observe in conclusion that what I consider to be novel and original, and therefore claim as the invention secured to me by the hereinbefore in part recited Letters Patent is:

First, the employment of a differentially wound indicating or regulating apparatus so connected to the conducting wires from a generator of electricity to a distant place as to indicate when the difference of potential between the two conductors leading to such distant place deviates from an assigned value at that distant place or to regulate the electricity, producing machinery in such wise as to maintain a constant difference of potential at a distance from the place of supply or generation of the current substantially as hereinbefore described with reference to Figs. 1 and 2 of the accompanying drawings.

Second. *In a system of electrical distribution or supply, the employment of three (or more) conductors in combination with two (or more) dynamo machines in series substantially as hereinbefore described with reference to Fig. 5 of the accompanying drawings, whether the middle conductor be continuous or be replaced by an earth return, as set forth.*

The third claim, relating to the method of removing a dynamo from the external circuit, or of changing a circuit from one dynamo to another by means of an automatic switch; and the fourth claim, relating to improvements in the meter described in Patent No. 49, of 1882, are struck out in the amended specification.

SUNSPOTS AND MAGNETIC DISTURBANCES IN 1892.*

BY M. RICCO.

Since the time of the apparition of the extraordinary sunspot of April, 1882, I have noticed that the passage of the large spots across the sun's disc have been often accompanied by magnetic disturbances. The same phenomenon repeated itself at the time of the passage of the extraordinary spot of February, 1892. Having received from the Washington Naval Observatory a copy of the photographic magnetograph curves showing the disturbances of 1892, by which we can determine the time of maximum, I compared this with the time of the transit of the principal sunspot at the minimum distance from the centre of the disc, that is to say, at the central meridian. It is not an easy or certain matter to determine the instant of maximum disturbance, since it results from the extraordinary and irregular oscillations of the declination (D) the horizontal component (F.H.) and the vertical component (F.V.) of the magnetism of the earth which do not always coincide. On that account I have limited myself to giving merely the hour at which the greatest deviation from the mean declination took place, near which also occurs the greatest variation of the two other components. I have reduced the time of the 75th meridian from Greenwich, adopted in the diagrams, to Catania time and I have compared the diagrams with the calculated time of the passage of the principal spot across the central meridian on the occasion of each disturbance. The following table gives a compendium of the numerical data obtained from the diagrams of the disturbances and from the calculations of the positions of the sunspots. The *excursions* are the amplitudes of the oscillations near the time of the maxima; and they are expressed in the case D in minutes of arc, and in the case of F.H. and F.V. in ten-thousandths of the C.G.S. unit. The diameter of the spots is expressed in terrestrial diameters:—

In 11 cases of magnetic disturbances seven took place after the passage of important spots across the least distance from the centre of the solar disc. Generally speaking, all the extraordinary, the strong, and very strong disturbances (except one) followed the passage of those spots which were, respectively, extraordinary, very big, and big; medium or feeble disturbances took place without the passage of sunspots.

All the disturbances were retarded in respect to the passage of the spots across the line of least distance from the centre of the solar disc. These retardations (except the second one) were comprised between the limits of 38 hours and 51 hours; the average being 45·3 hours, and as the synodic rotation of the spots is about 27 days = 648 hours, this retardation was only about one-fourteenth, and the deviations from the mean only a little more than one-hundreth of the time of rotation.

The figure annexed to the memoir shows this agreement of the six cases, and clearly proves that these positions of the spots on almost the same solar meridian, namely, that which is at a distance of 25deg. heliographic longitudes from the centre, at the moment of the maxima of the disturbances cannot be merely the result of chance.

This retardation of action upon the earth's magnetism of 45 hours 5 minutes indicates a speed of propagation from the sun to the earth of about 913 kilometres, that is to say, 335 times less than the speed of light.

We know, moreover, from the investigations of M. Wolf, of Zurich, that there is a perfect agreement between the period of the variations of the magnetic declination with that of the sunspots, and M. Garibaldi, of Genoa, has shown that this agreement is verified even in details. We know that Secchi and Tacchini have assumed for some time a connection between magnetic disturbances, the aurora borealis, sunspots, and solar protuberances. Finally, we know that in these spots there is vast movement and contact of vapours at different temperatures, which may well generate electricity, and the thickening of certain rays, particularly those of iron, which has been observed with the spectroscope, indicates a greater density, or, at any rate, a special condition of the vapour of this metal in the spots, which may also be the cause of the electric or magnetic action or induction which they exert on the earth when the spots cut, almost perpendicularly, the lines of force running between our planet and the sun.

For the present it is impossible to explain the disagreement of the retardation of the disturbance of January 29th. I intend to continue these investigations by going back to previous years.

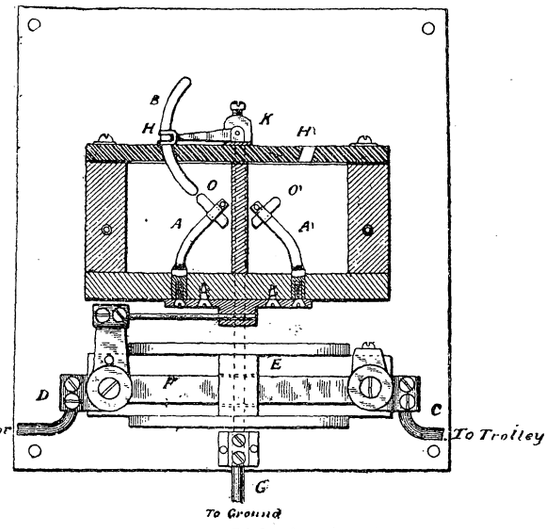
WESTINGHOUSE STREET-CAR LIGHTNING ARRESTER.*

The Westinghouse car lightning arrester, shown in the accompanying illustration, consists of two air chambers, A and A^1, having vents shown at H and H^1, through which the curved carbon, B, hinged at K, can freely pass, swinging from O to O^1. The carbon point O should be set so that it is separated from B when in its normal position, as shown in the figure, by one-sixteenth of an inch. The distance from O^1 to B should likewise be one-sixteenth of an inch when the curved carbon is in the other chamber. B is connected to G^1 and O and O^1 to D. F is a lead fuse, and E an insulating block provided with a slot through which the lead fuse is passed. The points C and D should be connected in series with the motor, and G should be connected to the ground, as shown in the figure. The action of the arrester is as follows :—

When a discharge takes place it passes through the lead fuse F to one of the carbons O or O^1, depending upon the position of B ; then across the air space to the curved carbon B, and from there to the ground, as shown in the figure. The dynamo current then following causes an arc to be established between the carbon B and O or O^1. The heat generated by this arc expands the air in the chamber, increasing the air pressure, and causes the carbon B to be instantly blown from one chamber to the other. This ruptures the arc and adjusts the arrester for the next discharge.

In the reported tests upon this arrester, 500-volt and 1,000-volt generators have been repeatedly short-circuited through it. In every case the circuit has been instantly broken without injury to



Westinghouse Car Lightning Arrester.

the dynamo, and the arrester has as quickly set itself in readiness for future use. In one of the tests made to demonstrate its promptness and reliability, carbons O and O^1 were so adjusted as to touch the carbon B in either of its two normal positions. A 1,000-volt generator was then short-circuited through the arrester, which resulted in the circuit being several times automatically opened and closed in one second without injury to either dynamo or arrester.

THE CONSTRUCTION OF TELEPHONIC APPARATUS.†

The French authorities have recently issued a circular to telephone makers, in which are laid down the conditions that will have to be fulfilled by their apparatus from January 1, 1893. The French Government, as is well known, have been operating the telephone system of the country ever since September 1, 1889. Instead of following the usual custom of telephone companies, who include in their annual rental the provision, fixing, and maintenance of their customers' apparatus, the French authorities decided to make the subscribers provide their own instruments. However, since the instruments purchased by the subscribers are kept in order by the authorities, no instruments are allowed unless well made, and capable of assuring good speaking. This way of going to work leaves the road open to the introduction of telephonic apparatus embodying all the improvements of inventors and manufacturers, and it is to be preferred to the system adopted by telephone companies, such as the English, for example, who when they have adopted a cheap type adhere to it and force it on their subscribers. But having made this rule the authorities found themselves involved in considerable difficulties in connection with the maintenance of the subscribers' telephonic apparatus, owing chiefly to the diversity of the parts. It is in consequence of this that they will impose the following rules on manufacturers, on and after January 1, 1893 :—

(1) All screws entering into the construction of telephonic apparatus must be to the standard gauge of the central depôt.

(2) Butt contacts are absolutely forbidden and are to be replaced by friction contacts.

(3) Spirals coming out from the cheeks of induction coil bobbins are to be done away with, and connection must be made with the coils by means of metallic blocks sunk in the cheeks.

(4) Only steel strips with platinised contacts to be made use of in connection with the telephonic springs.

(5) The spring of the movable hook should work in a normal manner when weights of from 200 to 600 grammes are attached to the hook.

(6) Wooden screws are to be replaced by metal screws or by bolts. The heads of the bolts are to be provided with lugs, and the nuts are to be grooved, so as to permit of their being screwed up by a screwdriver.

(7) All connections are to be made with insulated copper wire, covered with cotton or silk braiding, and ending in brass eyes. The braiding is to be red in the case of the primary circuit, blue for the secondary circuit, yellow for the bell circuit, and all three colours for wires common to all three circuits.

(8) The terminals are to be arranged and lettered, as shown in the accompanying figure.

(9) Only boxwood, thoroughly dry and sound, is to be used for the cheeks of the induction coils.

(11) Flexible cords are to be attached to the receivers by means of external terminals.

(12) The membranes of the receivers are to be varnished.

The following remarks are merely intended to be suggestive :—

(1) Split the heads of bolts to permit of screwing up by a screwdriver.

(2) Place the commutator hook on the left, which allows the speaker making use of the telephone to have his right hand free.

(3) Do not use for the receiver coils bobbins that split, but, on the contrary, use metal cheeks soldered to the cores, taking care to insulate this mass of metal from the wire.

All these rules explain themselves. The second, for instance, is explained by the fact that, contacts oxidising very easily with induced currents, it is advisable to use friction contacts which are automatically cleaned by each motion of the commutator hook. Subscribers will gain as well as the authorities by the application of these rules, since they are intended to prevent a host of little disturbances, the most evident result of which was to prejudice the subscribers whose service was momentarily interrupted, against the authorities.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, November 4th.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Presidential Address by Dr. John Hopkinson, F.R.S.

MONDAY, November 7th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ENGINEERS.

7:30 p.m. Paper to be read : "The use of Steel Needles in driving a Tunnel at King's Cross," by W. H. Holttum.

TUESDAY, November 8th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Address by Mr. Harrison Hayter, President, and presentation of Telford Medals and Premiums, and Miller Scholarship and Prizes awarded at the close of last Session.

THURSDAY, November 10th.

INSTITUTION OF CIVIL ENGINEERS.

9:50 a.m. Students' Visit to Tottenham and Forest Gate Railway.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. The following Paper will be discussed : "The Problems of Commercial Electrolysis," by James Swinburne.

FRIDAY, November 11th.

PHYSICAL SOCIETY.

5 p.m. Ordinary Meeting. Continued discussion of the Papers by Mr. Williams and Mr. Sutherland : "Dimensions of Physical Quantities" and "Molecular Forces."

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Two short Papers to be read on subjects connected with the testing and calibration of electrical instruments.

CYRUS W. FIELD.

With "THE ELECTRICIAN" for Oct. 28 was issued a Fine Steel-Plate Portrait of the late CYRUS W. FIELD, Pioneer of Ocean Telegraphy.

MUNICIPALISATION.

According to the old-fashioned notion, the duties of a municipality lay in the general well-being of the community to which it belonged, that is, it was to confine its attention to such works as the maintenance and cleansing of streets. The municipality was a consumer of gas and water, these being expended for the good of the ratepayers, but in no sense supplied to them. But now Local Authorities are beginning, and with great success, to undertake the business of purveying these and other commodities, and having once started as traders it is not easy to see where they will stop, for there is a wave of feeling in favour of municipalising many of those great industries which affect the convenience of dwellers in towns. It is urged that there is no reason why individual enterprise should be suppressed in favour of corporate action, for the whole world is open to the individual, while municipalities can engage in only a few businesses, and these are determined chiefly by considerations of price and uniform quality. It is not easy to define the direction in which the energies of these corporate bodies are at present tending. In Leeds and elsewhere the gas works have been managed with great economy, and the small profit has been applied to the reduction of the rates. We will not dwell here upon the contention that this is equivalent to selective taxation, for we wish to avoid the financial issues of the problem. The Corporation of Liverpool has carried out waterworks of immense importance, and the supply of electricity in the favoured parish of St. Pancras is

Hosted by Google

the envy of many a Londoner. Bradford, too, as far as the supply goes, has no reason to regret that the Corporation has made use of its Provisional Order, though it is difficult to see how future extensions can be made without materially altering the method of distribution. Of Brighton we cannot say much at present, except that the many criticisms of the municipal supply seem to be inspired by a rival company. However, with Derby, Portsmouth, Bristol, Cambridge, Dublin, Glasgow, and other schemes in progress and in contemplation, a fair comparison will soon be possible, and the weak points will be discernible while the strong points will, no doubt, be self-evident. "There is one matter," wrote Sir FREDERICK BRAMWELL to *The Times* in July, 1882, "in which, perhaps, a governing body may be allowed to be interested, and that is in the supply of water. There are two circumstances which render this different from any other kind of supply or trading—one is, that it is so unlikely as to be practically impossible that the commodity will ever be superseded, and the other is that on sanitary grounds it is necessary to charge persons for water on the basis of a rate, and not according to the quantity used." The first of these two reasons has been amply justified during the ten years which have elapsed since the date of this letter. Gas is not being superseded, but its uses are circumscribed and altered by the rivalry of electrical supply; and where gas works have been owned by the Corporation, and still more noticeably where members of the municipal body have been individually interested in gas works, powerful opposition has been offered to the introduction of electricity. Who shall say whether electric supply, as we know it to-day, will survive for fifty years? The second reason clearly fails to apply to electric energy except as regards street lighting. No objection can be raised to the proposed lighting of the Victoria Embankment and Westminster and Waterloo Bridges with electric light by the County Council. No private company cares about street lighting, and the convenient subways will allow it to be effected at a much cheaper rate than any of the supply companies could afford to accept.

It may be argued with much reason that when a municipal body enters into trade without competition, there is no inducement to keep down the price. Experience, so far, is opposed to this, for at St. Pancras 6d. is charged for ordinary supply and 3d. for current used during the hours of daylight, Bradford charges 5d., and the 7d. of the Brighton Corporation as against the 10d. of the private company is no doubt one of the causes of the jealousy to which we have referred. These three Corporations are doing very fairly well. The Bradford station began to pay in its second year. In the first three months' working at Brighton there was a loss of only £300, the usual sums having been set aside for sinking fund and interest. At present we are given to understand that a net profit of £70 per week is being earned. It must be remembered that stringent regulations for the payment of the sinking fund and interest are made under the Local Government Act, and a municipality cannot carry over sums in the convenient way so common with private companies. On the other hand there is a strong temptation to juggle with the various accounts of Local Authorities, especially in matters such as office and clerical expenses which are spread over several departments. But a strong point in favour of a municipal service is to be found in the low rate at which general management can be efficiently provided by a Corporation.

A more serious objection to a municipal supply than that of price is the absence of any incentive to improvement or encouragement of invention when a municipality carries on a business of this kind; and whether any undertaking should pass into the hands of a Corporation, Local Board, or Imperial Government may be judged by the opportunities which are offered in any particular case for option, discretion, choice, variety, and improvement. Water, it is generally admitted, should be of one quality, and that the best; this is only fair to those who drink it. Unfortunately no such simple standard can be applied in the case of gas, and when the quality must be continually watched, it seems better that a Local Authority should do the watching while a private company does the making, especially when a hundred-pound photometer and all its concomitant apparatus seems to be necessary for the examination. Leaving the vexed question of alternating *versus* continuous currents on one side, there are only three requirements in electric supply—continuity, uniform pressure, and cheapness. Any consumer of ordinary intelligence can judge of these for himself, and on these grounds, and these alone, may electric supply be accepted as a suitable business for municipal management. There is nothing to prevent private enterprise from competing with a Local Authority in electric supply by bringing in a private Bill. But such competition is discouraged by the Board of Trade, and on account of financial considerations such a course is very unlikely. An argument in favour of the municipalisation of such undertakings as those to which we have already alluded is the facility for raising capital at a low rate. Again, municipalisation is naturally very popular among contractors, since they get paid in cash and are not compelled to load their safes with ordinary shares. We should be sorry to see this carried to an extreme. Electric supply has been the outcome of individual enterprise. Great energy on the part of both financiers and engineers was needed, courage and skill were required, perseverance and hard work were essential. The labour was ordinary labour, engine building, dynamo making, trench-digging, cable making, and a dozen other well known operations were performed, and the labour was paid for at the ordinary rates. But capital, not labour, took the risk, supplied the scientific knowledge, and conceived the schemes; and is, therefore, as much entitled to reward as labour itself. Private enterprise has started the industry, and private individuals should benefit by the results. The encouragement of mere construction is hardly the same thing, and the best that can be said of the resolution of a Local Authority to undertake its own electric supply is that it is good for the electrical contractor.

The municipalisation of tramways and railways is a very different matter; it is of course altogether outside the categories suggested by Sir FREDERICK BRAMWELL, and fails to come under the test which we have suggested. Nothing but competition can ensure efficiency here, and we need only point to the disgraceful local railway service in Kent and some suburbs of London to prove this statement. Where trifling details conduce largely to convenience, where complications of through trains, season tickets, and a score of other matters of discretion exists, private enterprise, spurred by keen competition, will undoubtedly give the best results. It is on the other hand true that disaster has been averted from the Ship Canal by the Corporation of Manchester, and, as we are reminded by a very interesting article in the current number of the *Quarterly Review*, when there was a prospect of the abandonment of the Metropolitan Railway, the Corporation of the City of London, rather than see the scheme fall through, came forward with an offer of £200,000, and thus secured the prosecution of an enterprise which it had prescience enough to see would ultimately be to the advantage of the community.

Hosted by Google

Putting on one side the question whether, as a matter of principle, a municipal body has any business to embark in railway construction or tramway proprietorship, it is more than doubtful whether they should do so when the profuse promises of a modern prospectus fail to attract funds, and especially when, thanks to labour agitation and other influences, investors are looking everywhere rather than to industrial undertakings for the employment of their capital. If individual capitalists shrink from an undertaking, is it fair to risk the money of the ratepayers? The wave of feeling in favour of the municipalisation of everything does not alter the responsibility of the public body. The only man who is likely to escape immediate injury is the working man; capital may be squandered, but it goes into, or, at all events, *through* his pockets; the contractor may be ruined, but up till the very last Saturday he will pay wages, and the cunning man is he who seeks not to stem any particular tide of popular caprice, which may for the moment carry him off his legs, but contrive that it shall bear him, if not to the haven he intended, at all events to another as good.

REVIEWS.

The Science and Practice of Lighting. By W. H. Y. Webber. (London: Walter King.)

This book is mainly a reprint of a series of articles which recently appeared in the *Journal of Gas Lighting*, and is chiefly intended to give its readers an elementary explanation of the principles involved in the different systems of artificial lighting. With one or two exceptions there is no claim to originality in the treatment of the subject, but considerable credit is due to the author for collecting a large amount of useful information which has hitherto remained scattered in the pages of various periodicals. The first chapter is entitled "The Theory of the Radiation of Light and the Effect of Illumination." The fundamental terms are explained, and extracts are made, from the optical works of Lardner, Ganot, Parkinson, Heath and others, which expound these terms very clearly. A slip is made on page 6 in referring to Kepler's law, that the illumination caused by a light source varies inversely as the square of the distance from the light; for it is stated that "this proposition presupposes that the light source is perfectly regular—*i.e.*, radiates equally in all directions." This supposition is quite unnecessary, as the inverse square law holds whatever the character of the light, and only fails when the medium in which the light travels is an absorbent one. The style of the book on the whole is remarkably simple, only the slightest knowledge of mathematics being needed. While, however, in the first chapter, the term cosine is freely used, the explanation of this term is not given till almost the end of the book, when the simple trigonometrical terms are explained at great length. Under these circumstances an extract from Prof. Tait's book, occupying a whole page in the first chapter and involving not only cosines, but potential functions and double integrals, is peculiarly out of place. While the book is from one point of view commendably free from mathematics, the author gives up, as hopeless, several problems of no great difficulty, viz., the effect of a source of light with an appreciable area, instead of a mathematical point; the absorption and refraction of the atmosphere, the latter being indeed no great matter; and the effect of successive reflection. After quoting at considerable length from a no less antiquated authority than Dr. Lardner, the author exclaims "The difficulty of calculating the amount of this complicated reflection from reflection repeated *ad infinitum*, is evident."

The second chapter entitled "French Rules for Lighting" summarises the work of various French writers on illumination, such as Mascart, Montserrat, Brisac, Loppé, and Wybauw. Nearly all this information is to be found in the excellent treatise of Palaz on Industrial Photometry, but it has not previously appeared in English in book form, although some of it has been published in the pages of *The Electrician*, together with a problem by Mr. Loppé which, so far as the author knows, "has never before appeared in English." The third chapter deals with modern progress in scientific lighting and forms an interesting history of the successive improvements effected in gas lamps during the last 15 years owing chiefly to the growing competition with electric lighting. This chapter is mainly an abstract of contemporary articles in the *Journal of Gas Lighting*, and the author, who throughout the book shows a strong bias in favour of lighting by means of gas, holding up electrical engineers and their doings to derision, endeavours to show the advantages of greater subdivision of the light sources than is practicable with the electric light.

A critical chapter on modern practice follows, and this is perhaps the most important one in the book for electrical readers, as it is directly concerned with the relative merits of street lighting by gas and electricity. If a street is to be illuminated either by a few powerful electric lights or by many less powerful gas lights it is necessary in order to produce the same uniformity in the distribution of lighting that the electric lights should be placed on much higher posts than the gas lamps. Thus if the candle-power of the former, assumed to be equal in all directions, is 100 times that of the latter the one set of posts should be ten times as high as the second. With gas lamps of 16 c.p., and electric lights of 800 (mean) c.p., the ratio of the heights of the lamp posts should be 7 to 1. The usual practice is more nearly 2 to 1, so that the electric lighting would be more "spotty" than the gas lighting. The amount of uniformity which is desirable in street lighting is to a large extent a matter of opinion. It certainly varies enormously in different streets lit in the usual way by gas, and any attempt to obtain a numerical estimate of the quality of any kind of illumination from its variation from uniformity must needs be of very debateable value. Mr. Webber, however, makes the attempt; and advances the proposition that "the practical measure of the efficiency of the lighting is given by the difference between the brightest and the dimmest parts of the illuminated area." In order to understand this proposition, it is necessary to add that by the word *difference* Mr. Webber means *ratio*, and that the greater the index of efficiency the worse is the illumination. "With regard," says the author, "to the index of practical efficiency, which is the name here given to the difference between the best and the worst effects, it should clearly be kept as low as possible. It is hardly practicable to get it below 12 or 15, with cross or linear outdoor lighting respectively; and the best electric arc lighting in London runs it up to nearly 50, which should never be exceeded." Several practical examples of gas and electric lighting are then considered, and the calculation of the index of efficiency in these cases leads Mr. Webber to the conclusion that the former system is undoubtedly superior. One unfortunate electric system is discussed in which the brightness immediately under the lights is 300 times as great as that of the darkest places, and this is described as a degree of "spottiness" which a blind man could appreciate.

Mr. Webber's criterion of efficiency is not one which can be accepted without modification. Moreover, in applying it in cases where the illumination is calculated from the candle-power of the lights it must be remembered that in practice the dim light at the minimum between the lamps is generally increased by reflections or other circumstances extraneous to the lamps considered, and that in the case of arc lights the candle-power is not, as assumed in Mr. Webber's calculations, the same in all directions, but is naturally distributed so as to produce a more uniform illumination. That these effects have an important influence is shown by a calculation of the author's with reference to the electric lighting of Queen Victoria-street. He finds the ratio of the brightest to the dullest portions of this area to be 46·9, while it happens that actual measurements for this case show that the ratio is not more than 10, and about the same number represents the state of the lighting of Whitehall, which may be taken as an example of good gas lighting. The "index of efficiency" instead of being four times as great for arcs as for gas, as Mr. Webber makes out, is very nearly the same.

Hosted by Google

The book may be recommended to those who have already sufficient acquaintance with the subject to prevent their falling into such errors as those to which we have alluded, and who are not inclined to take up the contemptuous attitude towards electric light which is encouraged in its pages.

Induction Coils. By G. E. BONNEY. (London: Whittaker and Co.)

This handy little book is not in any sense a work on electromagnetic theory, but is—as it claims to be—a practical manual for amateurs, to guide them in the construction and use of induction coils and their accessories. Written in a clear and attractive style, the book may be understood by the veriest tyro in electrical matters; while it possesses the further merit of offering simple but good reasons for every direction which is given and for every property which is described. The early chapters deal with the phenomena of induction—which are explained by reference to a few well-chosen experiments—and with the practical details in the construction of coils for general and for special use. A short account is next given of some large and celebrated induction coils, and of their achievements; but mention might well have been made of the valuable assistance in chemical and physical research which these coils have given. Mr. Bonney has wisely devoted a portion of his work to an account of the construction of that accessory, without which the coil would be useless and on which the success of the experiments so much depends—the primary battery. Several forms are described, and their suitability to various classes of work is carefully pointed out. The work is copiously illustrated, and there is a good index. This volume will, no doubt, be welcomed by the amateur experimenter who desires to make his own induction coils.

Handbuch der Electrotechnik. By DR. E. KITTLER. Vol. I., Second Edition. (Stuttgart: Ferdinand Enke, 1892.)

The present volume is the first of a series of three, in which the author apparently aims at including all branches of technical electricity, and purposes to treat each one of them in a very detailed manner. The extent of his ambition may be gathered from the fact that he devotes 500 pages, in other words half, of the volume before us to the theory and construction of direct current dynamos. The book is written in the style which, unfortunately, seems to commend itself to most engineers; although it contains an enormous number of formulæ of all kinds, no attempt is made to prove a large number of them or to indicate the steps by which they are obtained. We may, however, remark that Dr. Kittler does give references to the original papers, thus enabling a student, after a vast amount of ransacking of public libraries and bookshelves, to satisfy himself as to the real meaning of the symbols and equations found in the work. Of course it may be said that the volume is a handbook and not a text-book, but we are nevertheless of opinion that the portions referring to matters of theory would be improved by treating of fewer points, but in a more complete manner. The descriptions and figures of machines and instruments are very numerous, and are quite equal to anything of the kind which we have previously seen; the woodcuts especially are well executed, and exhibit clearly all the parts of the machine they are intended to represent. The volumes are to be separately indexed, each containing an index of names and contents, so that each volume is complete in itself. This is an advantage often overlooked in similar handbooks. The contents of the first volume include the general treatment of magnetism and induction, electrical measurements, the measurement of mechanical work (this section being from the pen of Herr Schröter, of Munich), and the principles, theory and construction of direct current dynamos.

The Electric Lighting of the Embankment.—On the recommendation of the Highways Committee of the London County Council, it was referred to the Parliamentary Committee to take the necessary measures to obtain the sanction of Parliament in the next Session to the carrying out of the electric light installation on the Victoria Embankment and parks and gardens, and the Westminster and Waterloo bridges.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 609, Vol. XXIX.)

20. The Cable Ship "Faraday."—This vessel, which has laid six cables across the Atlantic, and carried out some important repairs in deep water, is of a very distinct type. She may be called one of the masterpieces of the late Sir William Siemens, who, in the year 1873, considered the practice unsatisfactory of adapting existing ships for cable expeditions, and thought that the requirements in such a vessel demanded a special design throughout. That his design of the "Faraday" fulfilled these requirements in a very marked degree time has amply proved. In the middle of 1873 the keel of this vessel was laid at the Walker Yards, Newcastle-on-Tyne, by the builders, Messrs. Mitchell and Co., and she was launched the following February. By the courtesy of Messrs. Siemens Brothers and Co. the writer is able to present some illustrations and particulars of interest. In the first place, she is remarkable for the exact similarity of bow and stern (Fig. 73), hand and steam steering gear being fitted at both ends, and enabling her to answer the helm equally well when going astern. Further, being a twin-screw boat, she can be turned in her own length, and manœuvred with great ease and promptitude. A wide central deck space from bows to stern has been provided by placing her funnels abreast instead of fore and aft, and by this means the cable has a clear run along the centre of the deck from the tanks to the sheaves.

Her dimensions are :—360ft. long, 52ft. beam, by 36ft. deep. Her registered tonnage is 5,000, and coal bunker capacity 1,700 tons. She has carried as much as 1,962 knots of mixed cable on one trip, the weight of this cable being 4,500 tons, and her large coal capacity enabled her on one occasion to stay at sea for a period of three months without recoaling. There are three cable tanks, all of 30ft. depth, and having a total capacity of 2,000 miles of cable. The after and midship tanks are each of 45ft. diameter, and capable of taking in 800 knots of cable each, while the fore tank is 37ft. in diameter, and can hold 400 knots of cable.

For repairing work this vessel is fitted with powerful picking-up gear—Fig. 75—capable of lifting 30 tons at a speed of one knot per hour. It is fixed on the middle of the upper deck forward of the bridge, is roofed over, and provided with raised platform, to which all levers and valves are brought within easy reach. This view shows the path of the cable on deck from bows to tank, passing on its way the dynamometer, drum and hauling-off sheave. The buoys on this vessel are provided with four chains hanging over the top half of the buoy at equal distances apart. These are fast at top and bottom ends, and pass through two rings set in the buoy. Two cross ropes pass through the same rings, and encircle the buoy horizontally. The rings are also used for making buoys fast to deck by chains, as seen in illustration. The buoy is picked up by the top cross rope, and the chains on buoy are convenient for hanging on to or attaching the bridle chain.

The dynamometer is similar in action to those already described, but has the external appearance shown (Fig. 76). The framework forming the crosshead guides for the sheave is built of iron plates, riveted together in the shape indicated, and for convenience in keeping cable at a certain height this framework stands about 16ft. high, and the sheaves on either side are mounted on high A frames to correspond.

The mounting of the bow and stern sheaves is specially designed to eliminate all side friction between the cable and cheeks of sheaves when the strain comes on sideways. The bow sheave is illustrated in Fig. 74, in which it will be seen that the sheave is mounted on a framework in bearings (A B) capable of turning sideways about a horizontal axis, so that in picking up or paying out, if the ship's course, owing to currents or weather, is not exactly in the same line as the cable, the sheave takes up at once the position of least strain. Further, by means of a chain attached to the framework at the lower extremity of the sheave on either side, the latter can be set up to any angle with the ship, and secured in that position if re-

quired. Both bow and stern sheaves are of precisely similar construction, the platform being right over the respective wheels, and built out a considerable distance from the ship. This vessel has seen good service in repairs to cables in the deep waters of the Atlantic. One specially smart piece of work was the repair of the Direct United States cable in a depth of 2,680 fathoms, when the whole operation took no more than 48 hours.

logs give only at their best the speed of ship through the water. What her speed is over ground as affected by leeway or currents the log cannot indicate, and, therefore, there has always been more or less uncertainty as to what slack is being payed out. In order to register correctly ship's speed over ground, Messrs. Siemens pay out alongside and simultaneously with the cable a pianoforte steel wire, which, having a breaking strain of 170 tons per square inch, is paid out perfectly taut, so that it lies with-

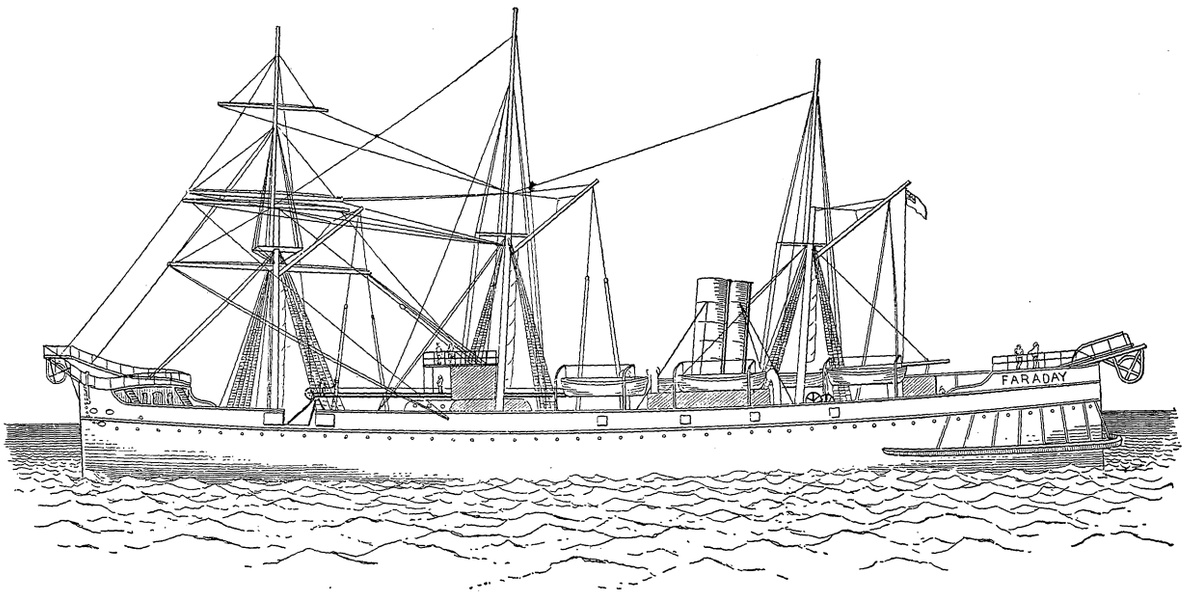

FIG. 73.—Cable Ship "Faraday." (5,000 tons.)

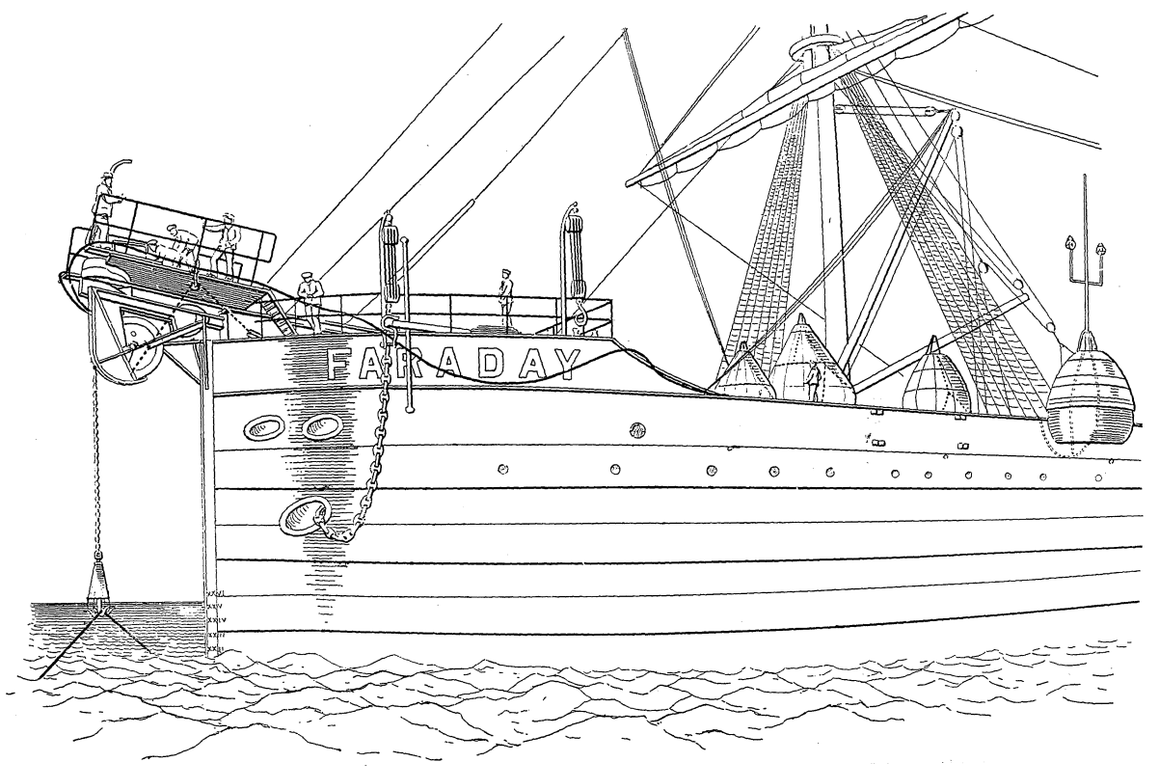

FIG. 74.—Bows of the "Faraday."

Turning now to the arrangements for paying out cable, it will be remarked that the vessel, as illustrated (Fig. 73), has a guard or crinoline fitted round her stern. The object of this was to prevent cable fouling the propellers, but after considerable experience it was found that the inconvenience of the crinoline was greater than its advantages, and it has, therefore, been discarded for some time. The paying-out machinery on this vessel is so constructed that cable can be laid with a fixed percentage of slack. The most approved automatic registering out slack on the sea bed. The excess in the length of cable over the length of wire payed out per hour at once gives the amount of slack. By an ingenious apparatus the percentage slack is continuously recorded. The two axles, whose speeds have to be continuously compared, namely, the axles of the wire and cable drums respectively, are caused to set in rotation two distinct parts of this apparatus, one being a wooden cone mounted on its axis between bearings, and the other a long screw, also mounted between bearings, and in a position parallel to the side of the

Hosted by Google

cone. The speeds of rotation of these two parts of the apparatus, which are quite independent of each other, are then proportional to the rates of paying out of wire and cable respectively. On the long screw is a circular nut, whose edge bears against the cone. If the cone was running slower than the screw, or say stopped altogether, the nut would run along the screw in one direction; but if the cone rotated, and the screw was stopped, the nut would be rotated by the cone, and travel along the screw in the opposite direction. Hence, the position of the nut is determined by the difference of speeds of the cone and screw, and its movements are indicated on a scale conveniently marked in percentages of slack. The brakesman can therefore adjust the brake on the cable drum as cable goes out, so as to pay out at a constant percentage of slack. By means of a train of clockwork and travelling paper-slip the nut is made to imprint a continuous record of the percentage slack paid out. The economy effected in cable payed-out amply covers the cost of the steel wire.

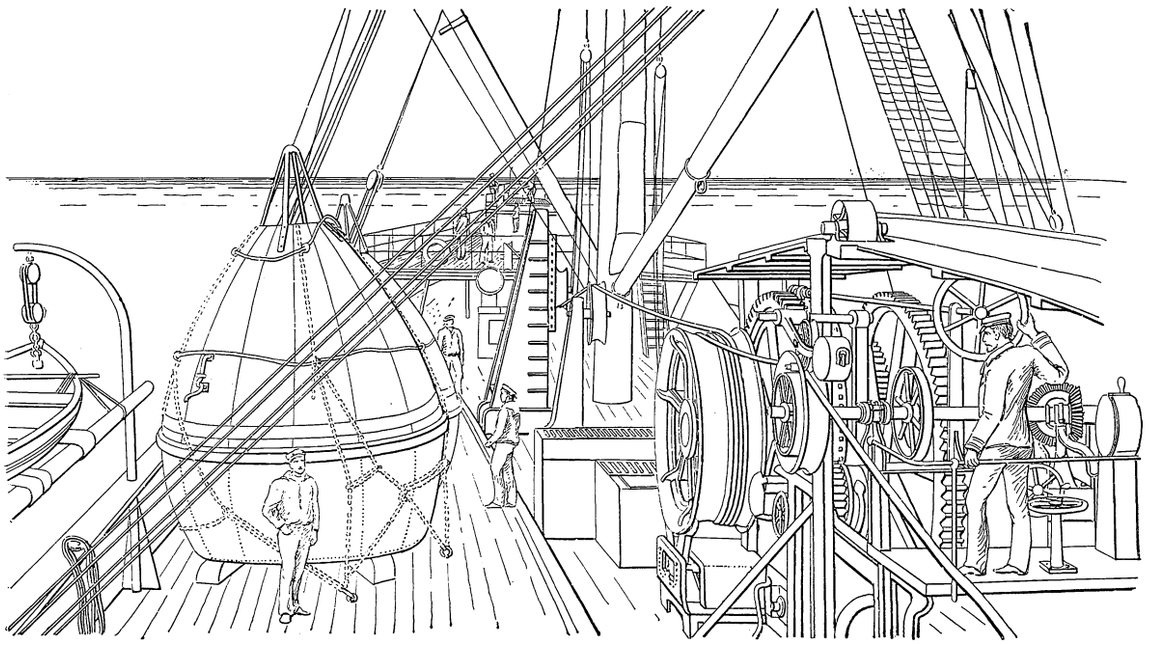

FIG. 75.—Forward Deck of the "Faraday."

The "Faraday" has made 23 cable-laying expeditions. The most noteable cables laid by her are mapped out in Fig. 77, her first expedition after launching being to lay the Direct United States cable in 1874 to '75, connecting Ireland (Ballinskellig) with the United States at Rye Beach, calling in at Tor Bay (Nova Scotia)—3,101 knots. In 1879 she laid a cable for the Compagnie Française de Télégraphe de Paris à New York, from France (Brest) to Boston (Cape Cod), calling in at St. Pierre (Newfoundland)—3,069 knots. In 1881 to '82 she laid two cables for the Western Union Telegraph Company from Cornwall to Canso (Nova Scotia)—5,107 knots, and completed these cables to New York in the year 1889 (1,577 knots). In the year 1884 she laid the two cables of the Commercial Cable Company from Ireland to New York and Ireland to Rockport, both cables touching at Canso, and it is remarkable that this large amount of cable (6,098 knots) was manufactured and laid within one year from the date of order. This vessel has therefore laid 18,952 miles of trans-Atlantic cables. The other cables marked on the map bring this total up to 20,130 miles, these being laid between St. Pierre and Louisburg, Brest and Cornwall, Waterville and Le Havre, and Waterville and Weston-super-Mare. When at home the "Faraday" lies in the Thames off Messrs. Siemens' Works, at Charlton Pier, Woolwich.

"Faraday," although smaller (1,385 tons). This vessel is stationed at Havre, and keeps in repair the two Atlantic cables of the French Company.

(To be continued.)

LEGAL INTELLIGENCE.

Hopkinson v. The St. James' and Pall Mall Electric Lighting Company (Limited).

On Wednesday last this case came before Mr. Justice Romer in the Chancery Division of the High Court of Justice, Sir R. Webster, Q.C., Mr. Aston, Q.C., Mr. Moulton, Q.C., and Mr. Hopkinson, Q.C. (instructed by Faithful and Owen), appeared for the plaintiff; Sir Horace Davey, Q.C , Mr. Finlay, Q.C., and Mr. Roger E. Wallace (instructed by Mr. A. C. Curtis-Hayward), for the defendants.

Sir RICHARD WEBSTER, in opening the case, said that his client, Dr. John Hopkinson, was Senior Wrangler, and for many years had occupied a distinguished position. He was well acquainted with all the modern developments and discoveries in electrical branches of knowledge. The plaintiff sued for infringement, and the defence was, shortly, that there was no invention, as the alleged invention was either obvious or invalid. The patent taken out by the plaintiff (No. 3,576*, 1882), was not a "casual" one, but was the outcome of much experiment and research. The patent in question was now equitably owned by the Westinghouse Company, but the legal estate was still vested in Dr. Hopkinson, and the Court of Appeal has decided that the action should be brought in his name. The specification, as amended in June, 1891, contained descriptions of two inventions. One of these, he alleged, was infringed by the defendants, and both were attacked by them in their defence. The plaintiff's system was known generally as the three-wire system of electric lighting by incandescent lamps. Dealing first with the principal invention. Here there was no substantial dispute as to the fact that if the patent be upheld the acts of the defendants amounted to an infringement of it. The case turned on the question of validity. In any system of electric lighting there must be a source of electricity, be it primary or secondary batteries or a dynamo; conductors or mains to conduct the electricity to the place where it was to be used and distributed, and lamps to utilise the electricity. In this case they have only to deal with the mains or conductors. He was not aware of any case of recent years in this branch of electric lighting. Before the date of Dr. Hopkinson's invention, one of the great objections to the introduction of electric lighting was the expense of copper, which was the metal most suited for conductors. The invention was described at he time as being most meritorious and useful. It fulfilled a want, and overcame a difficulty which had been long felt by men of eminence. This invention was made almost contemporaneously by Dr. Hopkinson in this country and Mr. Edison in America. On the latter attempting to patent it here he discovered he was forestalled by Dr. Hopkinson. It was important to remember this when his lordship considered the point made by the defendants that the alleged invention was obvious, and, therefore, not subject-matter for a patent. The current, from whatever source, on leaving the generating station, would be of a certain quantity and at a certain pressure—"pressure," or "difference of potential," as it was also called was measured in "volts." "A current of so many volts" meant a current at a pressure of so many volts. To borrow an analogy from hydrostatics, pressure corresponded to "head of water." It was most important to remember that in arc lighting the lamps were arranged "in series"—that is, that the whole current goes through each lamp in succession, while in the incandescent systems the lamps were arranged "in parallel"—that is to say, the whole current flowed from the generator in the main to the place where the installations were fixed; then it was divided and flowed through the lamps, each taking a portion, and then reunited and returned by the other conductor to the source of electricity, thus completing the circuit. The difference of potential or fall of pressure through each lamp should be the same, and equal to the difference of potential between the mains at the place where the installations were. But where lamps were placed "in series," as in arc lighting, the difference of potential between the mains is the sum of the differences of potential at each lamp; consequently, it was important in such cases to have the quantity constant, and the pressure varying with the number of lamps. In parallel lighting, on the other hand, the quantity of current varied, and the object was to keep the difference of potential at the installation end of the mains constant. [The learned counsel illustrated his remarks here and throughout his speech by reference to models.] These *desiderata* were known, and many skilled electricians worked at the problem, but none of them hit on Dr. Hopkinson's and Mr. Edison's solution. It was found that the cost of conductors could be lessened by conveying the current at a high pressure, and the device adopted was to arrange the lamps in a combination of "parallel" and "series"; a certain number were placed in series, and then several series so arranged were placed "in parallel," so that the current on dividing, when leaving the outgoing (or "flow") conductor, passed through several parallel sets of lamps in series on its way to the "return" conductor. The difference of potential required was much greater than in a purely "parallel" system, and thus the current could be generated at a much higher pressure. Taking the difference at the mains at 100 volts, then each series of lamps would consist of two 50-volt lamps or four 25-volt lamps, and so on. This device, however, did not secure equal difference of potential at each lamp, for the turning out of one series only caused a redistribution of current amongst the others. The fall of pressure between two points on a conductor measured in volts was equal to the product of the resistance of that part of the conductor in ohms by the current in amperes. As the resistance in each lamp was fixed by the dimensions of its filament, the amount of current passing through it was proportional to the difference of pressure. Hence, if this difference of pressure be not kept constant the current would vary; if too large it would destroy the lamp very soon; if too small it would not give light. Again, in a complete circuit, the total difference of pressure at the dynamo ends of the mains was distributed throughout the circuit in proportion to the resistances of its parts; that was to say, the fall in pressure along the circuit varied from point to point with its resistance. If the pressure at the engine-room be maintained constant, the turning on or off of house installations varied the resistance of the middle portion of the system, and hence varied the distribution of pressure throughout the circuit, and so varied the difference of pressure between the mains at the lamps. More lamps being turned on tended to diminish the effective difference of pressure. It was essential to keep the difference of pressure constant at the lamps, and not at the engine-house. Gentlemen of the greatest eminence had experienced this difficulty, but had not seen their way out of it. The plaintiff's invention consisted in using three conductors instead of two, coupled up with two dynamos "in series." One outer wire formed the "flow" conductor of one dynamo and the middle one the "return." The middle wire was coupled up as the "flow" conductor of the second dynamo, and the other outer one as its "return." Hence the middle one only served to convey the "balance" of the two systems, hence could be of much smaller dimensions. The house installations were distributed equally between the two systems (preferably house by house alternately), so that the result practically was that the dynamos worked "in series" and the middle conductor had not much current to convey. He was much honoured in his assistant [Lord Kelvin here assisted with the model], and he would now illustrate what he had said by the model. [Detailed experiments were then made.] When all the lamps forming one system were "off," it was reduced to the old two-wire system, but commercially and practically this never occurred. This invention had been very largely used and commercially successful. It was the most important invention in electric lighting since that of the incandescent lamp itself. [The learned counsel then read and commented upon the specification (see page 7) in detail.] The combination claimed involved two essential details—(1) two dynamos coupled in series, and (2) balance by arranging the consumers on either side of the middle conductor so that it had only to convey the "balance" current. It was the old system simply and solely with the addition of what was necessary to bring the balance back. What was the defence set up on this part of the case? The peculiar construction of certain well-known machines! He would postpone for the present dealing with that by simply remarking that if that were so, eminent electricians would have effected enormous savings by acting on that knowledge. There was no allegation of prior publication by description, but they alleged it was used publicly by Messrs. Crompton and Co. at the Alexandra Palace and at the Glasgow General Post Office. He must wait till they attempted to prove those and other instances they mentioned. Their assertion that the three-conductor system was known simply amounted to this, that the middle conductor in such alleged anticipations to which they referred, was the *return* for both dynamos, which is another matter altogether. He should claim for his client that his invention was one of high merit and great success, and was as much subject-matter for a patent as the whole train of those supported by previous decisions. The alleged infringement was admitted to this extent, that the physical arrangement of the defendants' system would be

Hosted by Google

an infringement of the plaintiff's patent if it could be supported as a valid one. He must now direct his lordship's attention to the second invention of the plaintiff's. This had not been infringed by the defendants, but they (and in so doing were quite within their rights) attacked the validity of the plaintiff's patent on the ground that this portion of his invention was not new nor subject-matter for a patent. In arc lighting the lamps were arranged in series, the whole current going through every lamp, the pressure required being the sums of that required for each lamp—in other words, a certain current being required, and the resistance of the circuit being increased with each lamp, the total pressure must be increased in the same proportion. In incandescent lighting, the lamps being arranged "in parallel," each lamp took its share of the current. To maintain a constant current in each lamp constant difference of pressures must be maintained. Hence constant difference of pressure between mains at installations was essential. The resistance of a conductor was a known thing. It was proportional to its length and inversely as its cross-section; hence in the mains the resistance of any part might be taken as proportional to its length. Now the pressure fell owing to increased resistance, hence there was a uniform fall of pressure along the "flow" main to the installations, and also along the "return" main from the installation to the generating station. It would be proved that this fall of pressure increased with the current. When more lamps were turned on they took more current, and, consequently, if the initial pressure be constant that at the installations would decrease. The greater the distance of the installation the greater the fall of pressure, and the greater the pressure necessary at the engine-room to compensate for it. When an installation was, say, 1½ miles away the engineer was much troubled about the pressure at the installation, the current took care of itself. Various devices were used to give this information, one by means of "pilot" wires from engine-house to the other end of the main. [The learned counsel illustrated this on the model.] The plaintiff's invention proceeded on different lines. He solved the problem by taking an old expedient and applying it in a new way to a new object. A "voltmeter" was an instrument used to measure differences of pressure between certain points. It consisted of a wire of known resistance wound round an electromagnet. If the wires of the voltmeter be attached to the ends of the mains in the engine-house, the total pressure of the current was thereby measured. Again, the fall in pressure along the main, whose resistance was known and constant, was proportional to the current passing along it. The plaintiff added to the ordinary voltmeter a short, thick coil, wound in the opposite direction to carry the whole or part of the main current. This coil produced an effect on the needle proportional to the fall of pressure in the main. The combined effect on the needle was that it indicated not the total pressure at the engine-house, but that pressure less the fall in he mains, so that the voltmeter, as improved by the plaintiff, indicated in the engine-house at once the pressure at the other end of the main where the installations were. The needle might be used either as an indicator, or else to regulate the current automatically by means of a relay or other device. [The learned counsel here explained the invention in detail by referring to the specification.] In considering this case they must be careful not to use the knowledge of 1892 in dealing with a publication of 1882. The plaintiff was dealing with something which depended on the customers and not on the engineer. It was quite a different problem from those arising in arc lighting. The defendant said: "No, these things were used before for a like purpose." "Yes," said the plaintiff, "but you never had an instrument devised for indicating in an engine-room the pressure at a distant point." In arc lighting the problem was to bring the carbons to, and keep them at, a certain distance apart by mechanical means. Here the indicator could be used to automatically regulate the current. There was no trace of any such arrangement having been used for a purpose like the plaintiff's. What did the defendants set up in their defence? First they set up six specifications as anticipations. He would show that they contained no such anticipations. They next said the device was well known, and relied on certain instances. These were the Brush, Crompton, Pilsen, and Siemens lamps, in all of which the function of the regulator was to bring mechanically together certain pieces of carbon, and had nothing to do with a varying pressure, each was applied to a separate lamp, with no indication how the combined effect could be read in the engine-room. There was no suggestion of its ever having been applied to a multicle parallel bridge. All they said was that the analogy of somewhat similar apparatus should deprive this of being good subject-matter for a patent. He knew of no case in which such would be held to anticipate. The alleged anticipations afforded no means of solving the problem. This patent was never challenged before. Dr. Hopkinson's invention was the same as a *subsequent* one of Mr. Edison's. Other electricians were at the problem, and thought *subsequently* they had invented it. He had not pretended to explain this case with scientific accuracy, and he protested against the speeches of counsel being fastened upon as declarations of their clients in regard to matters of scientific details. It was by the evidence, and by that alone, his lordship would be guided in his decision in this case.

The Court then adjourned until yesterday (Thursday).

London County Council v. Carwardine and Co.

This case, stated by a metropolitan magistrate on an information relating to an alleged "sky sign," came before Mr. Justice Mathew and Mr. Justice Bruce on Tuesday. Mr. Avory and Mr. Daldy appeared for the County Council; Mr. Pattisson (Mr. Poland, Q.C., with him) appeared for the respondents.

The structure in question is over the premises, 84 and 86, City-road, belonging to the respondents. It consists of a tower 50ft. high, composed of a framework and balks of timber 10in. square, braced together by other timbers and by iron rods. At its lower end is securely tied down to the girders which support the top floor of the premises. Rather more than half-way up the tower is a square gallery, with a railing consisting of large wooden letters, 3ft. 6in. high. At the top of the tower are windmill "floats" in a circle 28ft. in diameter, which are brought round to the wind in the ordinary way by a rudder. The rudder is necessary to enable the structure to be used as a windmill. The structure is provided with special mechanism and gearing to enable it to be used as a windmill, in particular a system of counterbalanced weights by means of which the floats of the mill automatically open and shut according to the force of the wind, so that they revolve nearly at a uniform rate. Over the roof of the premises was fixed at one time an arc light, which was used at night for lighting up the structure and the front of the premises. This was removed in December last. The windmill drives two pairs of millstones, which grind wheat into meal on the respondents' premises below. They will produce, with an ordinary wind, three to four sacks of meal a day. The windmill was used for hoisting weights from one floor to another; and also drives a dynamo which generates electricity for supplying light. The magistrate dismissed the summons, being of opinion that the structure must be considered as a whole, and was a windmill not within the Sky Signs Act, 1891. The County Council's contention was that the structure was a sky sign within this Act. The respondents contended that it was primarily erected and used for grinding meal, and generating electricity, and hoisting sacks, and that structures erected or used mainly or primarily for trade purposes, and not for purposes of advertisement, were not structures in the meaning of the Act, and that the Act, therefore, did not apply. The Court held that the structure was a sky sign.

Mr. Justice MATHEW said that as the structure now stood it was within the Act. The Court was not called on to express any opinion as to what would follow if the letters on the tail or rudder were painted over and those on the balustrade removed.

Mr. Justice BRUCE was of the same opinion.

Hooper v. The Western Counties and South Wales Telephone Company (Limited).

In the Chancery Division of the High Court of Justice, before Mr. Justice Chitty, on Saturday last, this case came on for hearing. The case involved an important question of Company law as to the meaning of the term "reconstruction of a company." It appeared that the defendant Company was a provincial telephone company, incorporated in 1884, with a capital of £400,000, divided into 20,000 preference shares of £5 each, and 300,000 ordinary shares of £1 each. The defendant Company had subsequently issued debentures to the amount of some £60,000 or £80,000. The plaintiff was the holder of nine debentures of the defendant Company of £100 each, bearing interest at 5 per cent. The debentures were redeemable at par in 1896, but there was a proviso that the defendant Company might, at any time after the expiration of one year from the date of the debenture, redeem the debenture by giving three calendar months' notice to the holder, and paying to the holder £105 for every £100 capital secured, with interest up to the date of payment. There was also a further condition that, if the defendant Company commenced to be wound up "otherwise than for the purposes of reorganisation or reconstruction," the principal money secured by the debentures was to become immediately payable. In June, 1892, a provisional "agreement for amalgamation" was entered into between the defendant Company and the National Telephone Company providing for the sale to the National Company of all the business and property of the defendant Company, in consideration of the allotment of shares in the National Company to the defendant Company's shareholders in exchange for their shares in the defendant Company, and also in consideration of a provision for the exchange at par of the debentures of the defendant Company for debentures of the National Company, or of a sum in cash equal to the par value of the preference shares and debentures held by persons not consenting to exchange. Special resolutions were subsequently passed by the defendant Company that the "agreement for the amalgamation of the two Companies by a transfer of the business and property" of the defendant Company be approved, and for the voluntary winding-up of the Company, and the appointment of a liquidator for the purpose of giving effect to the agreement and winding-up the Company's affairs and distributing its property. The large majority of the debenture-holders consented to the proposed exchange, and the remainder accepted the full par value of their debentures, with the exception of the holders of debentures to the amount of some £1,800, amongst whom was the plaintiff. The contention of the plaintiff was that the contract by the defendant Company to pay a premium of £5 for each £100 on redemption before 1896 was not rendered null and void by the liquidation, inasmuch as the transaction between the two Companies was merely tantamount to "a re-organisation or re-construction" of the defendant Company, and was within the exception of the condition specified. It was stated that the defendant Company was prosperous and solvent, and that the National Company was another telephone company with far wider operations and a far larger capital.

Mr. Justice CHITTY said that, on the face of the special resolutions, the purpose was to carry into effect an agreement for amalgamation. But the substance of the transaction was to be looked at, and it must be seen whether it was an amalgamation or whether the transaction fell within the words of the condition, and was a reconstruction or reorganisation of the Company. The words reconstruction and reorganisation had no technical meaning. No text-writer on company law, when writing on the reconstruction of companies, used the word "reconstruction" so as to include a transaction like that in question in the case before the Court. The condition in question plainly included a voluntary winding-up origi-

Hosted by Google

nating from the Company. There was one mode of reconstruction which might possibly be said to be within the strict sense of the term. That was when a company made an arrangement with its creditors by a voluntary winding-up under the Companies Acts, and then proceeded to stay the winding-up by means of an order of the Court or otherwise, and proceeded to reconstruct itself according to the arrangement or scheme and go on as the old company. That would certainly be reconstruction within the present condition. The Company would still continue to exist. But the meaning of the word could not be confined simply to a transaction of that kind. That would be too narrow. A company might adopt another mode of reconstruction. The Company might go into voluntary liquidation, and propose as a scheme for reconstruction the formation of a new company, the shareholders of the original company taking shares in the new company. There it was obvious that the original company did not continue to exist. Then there was in form a sale to the new members, and the original company in point of law ceased to exist. It might, no doubt, be said that there was no power in such a case to compel dissentient members to come in, but such a scheme was not put on foot until practically it had been ascertained that the old shareholders would come in. Mr. Palmer, in his work on company law, used throughout the word reconstruction as referring to the plan of forming a new company to take over the business of the old company, and he treated it as essential to a scheme of reconstruction that a new company should be formed. The same text-writer, when subsequently dealing with amalgamation, treated that as a sale by a liquidating company of its assets to another existing company for shares in the latter company. Another writer treated reconstruction as the transfer of the assets of an old company to a new company formed for the purpose of acquiring its business. Other writers wrote to a like effect. The clue to the meaning of the word as used in a clause like the present was whether a new company was practically the same as the old, even although in law it was a separate corporation. In the present case the transaction was not a reconstruction. With regard to the term reorganisation, it appeared to him to be merely an alternative expression, or anyhow, to be used in no wider sense than reconstruction. The present case was that of a comparatively small company joining with a comparatively large company, and the transaction might be compared with that of, say, a great railway company buying up a small railway company on terms that the shareholders of the small company should receive shares in the larger company. If the scheme was sanctioned by Act of Parliament and the shares accordingly allotted, would any reasonable person call that a reconstruction of the small company? It appeared to him that such a term would be wholly inaccurate. The illustration was analogous to the position of the two companies in the present case. The view he took was that the defendant Company had not undergone reconstruction, and the plaintiff's proceedings must be dismissed with costs.

Telephone Rentals.

At the Sheffield County Court, on Saturday last, the National Telephone Company sued George Bramhall, fishmonger, of the Market Place, for a half-year's telephone rent, due June 30th last. An agreement produced by the plaintiff Company showed that the defendant had agreed to pay £8. 10s. per annum, but the defence now set up was that the defendant took the telephone on a then reduced rental of £8. 10s., in order to induce customers to take it, and that by verbal arrangement with Mr. Tasker, of the Sheffield Telephone Exchange, it was agreed that he should give it up whenever he liked, without notice. When the Sheffield Exchange Company was taken over by the National Company he gave notice to have the telephone taken away, but the Company sued under the agreement, although the rent had been reduced since it was drawn up. The case was ultimately adjourned.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October* 21, 1892.

New York Street Railway Franchises.—Mayor Grant signed all the nine street railway franchises which were recently passed by the Board of Aldermen with the exception of one, granting the privilege to the Metropolitan Traction Company on 9th Avenue; this was returned to the Board with the request that it be reconsidered. At a meeting of the Board of Aldermen, held on Monday of last week, that franchise was reconsidered, and passed with the following amendment:—"After the words 'to be operated by power other than horses or locomotive steam power' to be inserted the words 'or the power known as the trolley system, or any motive power operated by means of electricity through an overhead wire.'" This action will prevent the Metropolitan Traction Company from operating any of its proposed extensions by the trolley system. That Company states that the cable system will be introduced, but it is probable that at least the 9th Avenue Line will not be equipped until public opinion has changed sufficiently to admit of the employment of the trolley.

Storage Battery Traction in New York.—Some time ago it was rumoured that the Second Avenue Surface Line was to be equipped with the storage battery system, but at that time the report could not be confirmed. It is now definitely announced that the Waddell-Entz Company is to place in active service upon that route 10 cars equipped with storage batteries and motors of their own manufacture. A power house is to be erected immediately. The generators will be of the Waddell-Entz type, directly coupled. The Waddell-Entz battery uses copper for the positive and iron for the negative plate, and the liquid is a zincate solution of potash. The containing box is of iron instead of hard rubber or glass, as is usually the case. The voltage of this cell is very low, and it is claimed that a discharge rate of 1,000 amperes can be maintained without injury to the cell. The weight for a given output is considerably less than is the case with the ordinary lead batteries. The motors are of the gramme ring type, with single reduction gear, and very low speed. The controlling device will, it is understood, regulate the speed by grouping the batteries; and it is proposed to make use of the momentum of the car in going down hill to recharge the cells. The result of this practical application of the storage battery to traction work will be awaited with considerable interest. Thus far the storage battery has not proved successful from an economical standpoint in this country, although it has been given several very fair trials. This line, however, will offer an unusually good opportunity to test the merits of this system, as it is practically level, and the traffic is comparatively heavy.

The New York-Chicago Long Distance Telephone.—On Tuesday of this week the long distance telephone line between New York and Chicago was formally opened by Mayors Grant and Washburn in their respective cities. Conversation could be heard over the line almost as distinctly as on the ordinary local telephone. One of the interesting incidents connected with the opening was the talking from the New York end of the line of Prof. Alexander Graham Bell with Mr. Wm. H. Hubbard at Chicago, who assisted Prof. Bell in the installation of the first telephone line ever erected, at the Centennial Exposition in 1876, and with whom he had not conversed through a telephone since that time. The line is constructed of No. 8 hard drawn copper-wire, weighing 435lbs. to the mile. The utmost care has been given to the matter of insulation, and the use of cables has been avoided wherever possible. The two wires forming the circuit are run on what is called the balance principle, that is, the wire from New York passes on the north side for a short distance, then crosses to the south side, then back to the north side again, and so on. The transmitting instrument is the ordinary long distance telephone. The length of the line is about 950 miles, which is more than twice the length of the longest line which existed prior to its completion. The line passes through Easton, Harrisburg, Pittsburg, Newcastle, Youngstown, and other cities, with branch lines to Cleveland and Toledo. The New York end is connected with almost all of the more important cities of the East, including Boston, Philadelphia, Baltimore, Washington, and Buffalo, so that all of the important points in the section through which the new line runs are now in telephonic communication.

CORRESPONDENCE.

BARE COPPER UNDERGROUND CONDUCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A good deal has recently been written on the heavy leakages and other troubles due to electrolysis which have taken place in the underground main system employed by several of the Paris Companies. This has been attributed to the extensive use of bare copper conductors supported on insulators. We take this opportunity of pointing out that such troubles have not occurred in England, although the use of bare copper conductors has been very extensively adopted in London and in other towns. As we were the pioneers in the matter we wish to explain the points wherein our success-

Hosted by Google

ful English practice differs so very completely from the unsatisfactory practice that has been adopted in Paris.

Seven years ago, when we were responsible for the design as well as for the contract for the works of the Kensington and Knightsbridge Company, we proposed to the Directors the use of bare copper conductors, and accepted all the heavy risk and money responsibilities which such a novel system of underground conductors would have entailed if it had turned out to be a failure. Now that its success has been proved we consider we are entitled to whatever credit and saving has attended the system.

In working out our system of bare copper underground mains we, at an early date, saw the absolute necessity of so arranging the insulating supports that everyone of them could be instantly accessible for the purpose of being cleansed or replaced. We therefore devised means of putting our conductors under considerable strain so that the number of insulating supports could be reduced to about 120 per mile, that is about 14 yards apart, instead of being spaced about 2 yards apart as is necessary if the bare conductors are supported on mere notches in earthenware or other insulating bridges. Those who have examined our system in the West End of London and elsewhere will have noticed at intervals of about 14 yards the covers of the openings at which access can be given to every insulator. We use separate cylindrical insulators of the lipped or telegraph form, one for each conductor, which gives great insulating surface and prevents the accumulation of moisture, and as a result we can guarantee a degree of insulation that is quite impossible when a large number of mere notched insulators are used even when the latter are quite new. Our system, commenced seven years ago, has yielded unexpectedly satisfactory results. The means that we have adopted to prevent the access of water and gas have been perfectly successful, the insulation resistance of the whole system has been far higher than has ever been the case where continuously insulated cables were used, for reasons which will be readily understood by those practically acquainted with the maintenance of an underground network connected direct to the houses. All practical engineers in charge of such systems know that 90 per cent. of such leakage as exists on a supply company's system occurs either at the junction of the house service lines to the company's mains or on the service lines themselves just within the consumers' premises. As in our bare-copper system these junctions are made in the street boxes and can be instantly examined or detached for testing purposes, it is found in practice that the localisation of leakages is greatly simplified, and hence the leakage itself greatly reduced.

If we are right in insisting that the culverts should be made impermeable to water and gas and that the insulators should be so arranged as to give great insulating surface and be completely accessible for cleansing and repairing purposes, it will be seen that the troubles in Paris can be readily accounted for. The Paris engineers came over to see our system during its earlier stages and copied it in some respects, but in others fell into the very errors that we had already avoided. They still continue to use a great number of insulators placed close together, these insulators being of a poor insulating quality, and the great majority of them being completely inaccessible. They take no pains to make their culverts impermeable to water and gas and no arrangements have been made to enable them to inspect or clean their system. We think that the unsatisfactory results in Paris should be a warning to some English engineers who appear to think that the good results we have obtained can be equally well obtained by the use of mere notched insulators placed close together, but we very much fear that the great reduction of surface and difficulty in keeping these surfaces clean will cause a repetition of the Paris troubles. The fact, however, has now been proved beyond doubt that a well-designed bare copper underground system is superior to any existing system yet tried for a low pressure distribution network. Such a system costs less for maintenance, testing, cleaning, and coupling up to than any other system with which we are acquainted.—Yours, &c.,

R. E. Crompton, Managing Director

London, E.C., Nov. 1, 1892. (Crompton and Co., Limited).

THE LOWEST TENDER.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I venture to make a few remarks on the subject of the "lowest tender," dealt with in the article you quote from the *Engineer* this week. I think the true and fair solution is that arrived at by the writer, viz., to always state clearly that the lowest tender is not entited to acceptance as a matter of right, when firms who incurred expense in preparing estimates could do so at their own risk and with their eyes open. There not only are, but there undoubtedly ought to be, many reasons besides price to influence the engineer who has to make the selection, and this may be so even when the firms tendering are of similar reputation. The trouble lately has rather been that the lowest tender has been accepted blindly irrespective of the question whether it was possible to do good work at the price.

But there is one crying evil which does call for immediate remedy. I refer to the plan of inviting tenders to give an appearance of impartiality when it has been already settled privately who is to have the work. There is no doubt that this does occasionally take place, and no one will deny that it is most unjust to a firm which has gone to expense in preparing a tender that is not intended to be seriously considered.

A further matter is the question of deposits on applying for specifications. Now the only legitimate excuse for these is to avoid expense being caused by bogus applicants. For this one guinea is amply sufficient; and we ought to have no more of these three and five guinea deposits. It is enough to put the contractor to the expense of tendering, without trying to make money out of him as well.—Yours, &c., Russell.

Amberley Cottage, Maidenhead, Nov. 1, 1892.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Tenders Invited.—The Magistrates and Town Council of Paisley invite tenders from companies or persons willing to take over the powers contained in their Electric Lighting Order, 1891. Further particulars are given in our advertisement columns, and all information can be obtained from Messrs. Young and Martin, Town Clerk's Office, Municipal Buildings, Paisley. The tenders must be in by the 28th November.

——— The Commissioners of Hove, Sussex, are inviting schemes, accompanied with plans, specifications, and tenders for wiring the Town Hall, and for providing fittings and lamps. Further particulars are given in our advertisement columns, and tenders must reach Mr. H. Endacott, town clerk, Hove, not later than the 8th inst.

——— The Stornoway Pier and Harbour Commissioners invite tenders for the supply of greenheart timber. Tenders must be sent in to the Secretary of the Pier and Harbour Commissioners by the 18th inst.

——— The Midland Railway Company invite tenders for the supply of various stores, including telegraph instruments, wire, &c. Tenders must be in by 9 a.m. on the 10th inst.——The Great Northern Railway Company of Ireland invite tenders for the supply of various stores during the year 1893, including brass and copper sheet, tube and wire, india-rubber goods, iron tubes, and wire, &c. Tenders must be in by the 21st inst.——The Cheshire Lines Committee also desire tenders for the supply during 1893 of general stores, including telegraph materials (instruments, wire, &c.), wrought-iron tubing, galvanised iron wire, &c. Tenders to be in by December 3rd.

——— The Direction-Générale des Postes et des Télégraphes of France invite tenders for the supply of annunciators for telephone offices. Applications for permission to tender must be made to 103, Rue de Grenelle, Paris, before the 6th inst., and the adjudication will take place at 11 a.m. on the 16th inst.

——— Tenders are invited for the electric lighting of the towns of Orihuela and Huesca, in Spain, offers to reach the municipality by the 19th and 21st inst. respectively.

Change of Address.—Messrs. Hodges and Todd have removed their works from 19, Kirby-street, to larger premises at 82, Turnmill-street, E.C., owing to increased business. A considerable extension of manufacturing plant has been put down.

Hosted by Google

VACANT APPOINTMENT.—The vestry of St. Pancras require a dynamo and switch-board attendant for their Regent's Park Station. Applications, with particulars, must be sent in to Mr. Pyecraft, Chief Clerk Electricity Department, Vestry Hall, St. Pancras-road, N.W.

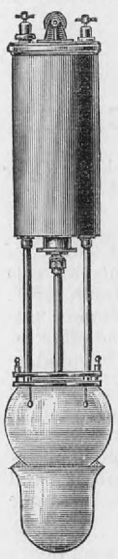
——— We would remind our readers that Wednesday next, the 9th inst., is the last day for sending in applications for the appointment of electrical engineer, required by the Oldham Corporation.

DISSOLUTION OF PARTNERSHIP.—We are asked by Mr. Rashleigh Phipps to notify that by mutual consent the partnership hitherto existing between Messrs. Rashleigh Phipps and Dawson has been dissolved. Mr. Rashleigh Phipps has started business under the title of Messrs. Rashleigh Phipps and Co., at 102, Oxford-street, W.

ECLIPSE ELECTRIC LIGHTING SYNDICATE (LIMITED).—At meetings held on October 6th and 25th, a resolution was passed and confirmed that the Syndicate be voluntarily wound up, and that Messrs. John Garford, 3, Vernon-chambers, Southampton-row, W.C., and W. H. Powers, 2, Pancras-lane, E.C., be the liquidators.

INTERNATIONAL ELECTRIC SYNDICATE (LIMITED).—A petition for the compulsory winding up of this Syndicate was presented on October 25th by Mr. G. H. Hodgson, of Shipley, and will be heard at the Royal Courts of Justice, London, on Wednesday next, the 9th inst.

MESSRS. EVERED AND CO. (LIMITED).—In an article in our issue of October 21st reference was made to a new wall socket made by this firm, but we omitted to call attention to the special device by which short-circuiting is completely obviated. By a simple contrivance on the base of the socket, short-circuiting is rendered impossible, even as the result of an accident. This is a feature which Messrs. Evered and Co. claim no other wall socket, either with or without switch arrangements, possesses, and for which their instrument has been particularly designed.



THE BROCKIE-PELL ARC LAMP.—Messrs. Johnson and Phillips send us particulars of a new type of the Brockie-Pell arc lamp which they have specially designed for the lighting of shops and similar establments, where space is of considerable importance. The lamp, which is focussing, gives a perfectly steady light with either continuous or alternating currents of from 5 to 10 amperes, either in parallel, with 50 volts, or 2 in series with 100 volts and upwards, or any number in series. Our illustration shows the lamp on a scale of about one inch to the foot. No less than 50 of these lamps have been installed at the extensive stores of Messrs. Jones Brothers, Holloway-road, London, N., in the installation which Messrs. Sharp and Kent have recently completed, and which forms one of the best lighted groups of shops in the Kingdom. The lamp sells complete at £10.

ELECTRIC LAUNCHES.—Messrs. Woodhouse and Rawson United (Limited) have received instructions for the construction of a new launch for Mr. J. West. The launch is to be 35ft. in length, and will be built to travel fast. Inquiries regarding electric launches are, we understand, increasing from all parts of the world.

LITHANODE AND GENERAL ELECTRIC COMPANY (LIMITED).—This Company have just issued illustrated particulars of their batteries, and the uses for which they are specially designed.

MESSRS. W. H. ALLEN AND CO.—This firm have just issued their new illustrated catalogue of patent dynamos and high-speed engines. A set of useful tables accompanies the catalogue. Several of Messrs. Allen and Co.'s special makes of dynamos and engines in a separate and combined form are shown, including direct-acting engines and dynamos for cargo boats and yachts.

NEW EDISON AND SWAN SERIES LAMP AND HOLDER.—We are compelled to leave over to our next issue a detailed account of a new Series Lamp just brought out by the Edison and Swan Company. These lamps are of the ordinary 3½ watt type, and are made in two sizes, for 6·8 and 10 amperes, stock sizes being 16, 32, and 50 c.p.

HENLEY'S CABLES.—The Paper read by Mr. Preece upon the Specification of Insulated Conductors has resulted in a marked improvement in the arrangement of Cable Price Lists. We have received from W. T. Henley's Telegraph Works Company a copy of their last list, in which we find all the information that can be desired. The particulars of the conductors themselves are repeated on each page ; the thickness of the insulation is given in every case, which, with the megohm test, clearly defines the qualities of the various types of cable. We recently alluded to twin flexible cords, and of these a great number of varieties are given. The pure rubber classes are composed of 23, 35, 70, and 130 strands of No. 40, while a new class, covered with vulcanised rubber, 300 megohms, contains 12, 18, 36, and 61 strands of 0·008, a size between No. 35 and No. 36, S.W.G.

"EXCELSIOR" WICK CARBONS.—We have received printed particulars, giving sizes and prices, of the "Excelsior" wick carbons manufactured by W. Grüdelbach, of Dinslaken-on-the-Rhine, and for which the "Excelsior" Carbon Company, 80, Queen Victoria-street, E.C., are representatives in this country. Mr. Grüdelbach claims that by his special dry process of manufacture many advantages are secured to carbon consumers, and in particular that the carbons give a very steady white light and are very durable. Testimonials from Herr Krupp, and from the Royal Institutions of Electrical Engineers at Munich and Magdeburg, accompany the particulars.

SCIENTIFIC NOVELTIES.—The General Electric Company forward us a price list of scientific novelties which they are bringing out for the Christmas market. Amongst the novelties illustrated are several mechanical toy tools. These models are all worked with toy motors from E.C.C. dry batteries. The list also gives illustrations of the E.C.C. night light.

THE ELECTRICAL TRADES UNION.—A public meeting, under the auspices of the above Union, was held at the Tate Institute, Silvertown, E., on Monday last.

ASTON.—The new Technical School at Aston shortly will be commenced, and will be lighted throughout by electricity.

BELFAST.—The subject of electric lighting has taken strong hold of the Belfast public, and as a preliminary to its introduction for the lighting of the district, Mr. John H. Greenhill, who is well known to many of our readers, will give a lecture on electric lighting, which will include a number of illustrated experiments. A number of gentlemen, including Profs. Fitzgerald and Everett, will join in the discussion.

BUXTON.—A Committee has been appointed to make inquiries as to the cost of supplying the electric light to the district of the Buxton Local Board.

COLCHESTER.—A special committee of the Colchester Town Council which was empowered to go to the expense of £150 in obtaining a Provisional Order have reported that the cost would be £300. Additional powers to expend that amount have been accorded them.

EASTBOURNE.—The Board of Trade have notified the Eastbourne Town Council that they are satisfied that the Eastbourne Electric Light Company are in a position to discharge the obligations imposed under the Eastbourne Electric Light Supply Order, 1890.

ELECTRICITY POPULARLY EXPLAINED.—Mr. Alfred Slatter is contributing a series of articles on the Electric Telegraph to the *Church Monthly*.

HECKMONDWIKE.—The Electric Light Committee of the Local Board, at their meeting last week, instructed the clerk to write to a number of firms for the terms upon which they are prepared to put down an electric lighting plant at their own cost, and to supply the electric light, leaving power for the Board to purchase the plant by agreement at the end of a term of years.

HULL.—Reports from Hull regarding the electric lighting installation state that the Electric Lighting Committee, at their meeting on Thursday last, received a large number of applications for the light from leading firms in the district, and also from the local School Board. It is anticipated that as soon as the central station is ready, previous applications for the light will almost exhaust its capacity.

HOTEL LIGHTING.—The Great Northern Railway Company have recently bought and completely renovated the old Victoria Hotel at Bradford at a cost of £40,000. The hotel is lighted throughout by electricity, nearly 600 incandescent lamps being installed.

ILFORD.—The Ilford Local Board has agreed to receive a deputation of the ratepayers on the subject of the electric lighting of the district at their next meeting.

JOHANNESBURG (S. A. R.).—A large new building has been erected as an assay office and laboratory for the Standard Bank, which has been equipped in a most complete manner. Messrs. Johnson and Matthey have supplied the necessary assay apparatus. The electrical fittings, including bells, lighting, telephones, and lightning conductor, have been supplied by Mr. R. Lewis Cousens, the representative of Messrs. Woodhouse and Rawson United (Limited) at Johannesburg. The technical manager of the office is Mr. Cross, who was formerly with Messrs. Johnson and Matthey in England, and is the son of Mr. Andrew Cross, celebrated in the early part of this century for his researches in electrolysis.

LANCASTER.—The Lancaster Corporation are the owners of the borough gasworks, and have also powers to supply the town with electricity. A sub-Committee of the Corporation who have visited the various central stations in England and submitted a report

Hosted by Google

recommend the adoption of the low tension system. We understand that complete schemes and detailed specifications for the lighting of the borough and estimates of cost are to be invited from the Brush Company, Messrs. Crompton and Co., and Messrs. Mather and Platt. The report was adopted.

LIGHTING THE GUILDHALL.—At a recent sitting of the Court of Common Council it was agreed that £1,750 should be contributed towards the cost of an installation of the electric light at Guildhall, and that £500 per annum should be allowed for current and maintenance. The work is in the hands of Messrs. Lund Bros.

METROPOLITAN ASYLUMS BOARD.—At a meeting of the Metropolitan Asylums Board on Saturday last, the North-Western Hospital Committee asked for authority to obtain expert advice on the subject of the lighting of the hospital by electricity. Complaint was made that it is necessary to supplement the gas lighting by oil lamps, and that before making any recommendation on the subject the Committee would prefer to have advice. Permission was granted.

MILL LIGHTING.—Mr. G. Combe, of High-street, Belfast, has just completed an extensive installation of the electric light at Mr. Abraham Wilson's Spinning Mills at Newry, Ireland. One of Holmes's "Castle" dynamos is used, power being obtained from the mill engines. About 220 incandescent lamps are used.

MUNICIPAL LIGHTING.—A sub-Committee of the Local Authority of Newport, Mon., visited the St. Pancras electric lighting station last week for the purpose of making inquiries with regard to the proposed installation of the electric light at Newport. A similar visit was paid by the Hampstead Vestry, who also have in contemplation the introduction of the electric light.

NORTH BIERLEY.—At the last meeting of the Local Board it was decided to appoint a committee to consider the question of lighting by electricity, and to report as to the advisability of applying for a Provisional Order.

PERTHSHIRE.—As previously mentioned in these columns, the extensive Mansion House of Demalistair, occupied by Mr. Bunting, has been lighted throughout by electricity. Water-power is used, two 12⅓ H.P. turbines having been supplied by Messrs. Gilbert Gilkes and Co., of Kendal. Edison-Hopkinson dynamos have been supplied, the electrical plant having been erected by Messrs. Mavor and Coulson, from designs by and under the superintendence of Mr. Angus Murray. The installation has cost about £3,000.

SHOREDITCH.—The report on the electric lighting of the parish is postponed until the next meeting of the Vestry.

SHIP LIGHTING.—The new fleets of steamers now building at Belfast for the Pacific Steam Navigation Company, and for the Union Steamship Company, are all being installed by Messrs. W. H. Allen and Co. with their complete system of electric lighting, including engines and dynamos of their own make.

WILLESDEN.—The Willesden Local Board have intimated that they contemplate applying for powers for supplying the electric light in the district. This notification has been made in response to a request for their support to an application by a private company.

COMPANIES' MEETINGS & REPORTS.

Eastern Extension, Australasia and China Telegraph Company (Limited).

The thirty-eighth ordinary general meeting of this Company was held on Wednesday last at Winchester House, 50, Old Broad-street, Sir John Pender, G.C.M.G., M.P., presiding.

The SECRETARY (Mr. F. E. Hesse) read the notice calling the meeting and the minutes of the previous meeting, which were signed by the Chairman as correct.

The Directors' report and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen—I shall, as usual, give you some details, as to the working of the past half-year. The gross receipts for the half-year under review have amounted to £246,988, against £264,878 for the corresponding period of 1891, showing a decrease of £17,890, of which over £8,000 is due to "loss on exchange," and the balance to the reduced rates with Australia. (At this point Lord Tweeddale entered the room, and was cordially welcomed by the shareholders, most of whom were aware from the evening newspapers that his lordship had been one of the passengers by the ill-fated Scotch express, which came to grief near Thirsk the same morning.)

The CHAIRMAN, continuing, said: I am sure, gentlemen, that you will join me in congratulating Lord Tweeddale, who was unfortunately in the sad disaster that has taken place at Thirsk. I am sure he has made a considerable sacrifice to come here to-day, and I think we may congratulate not only ourselves but also him in having had such a narrow escape (applause). With regard to the falling off in the receipts from the Australasian traffic, it is proposed, at the request of the Colonies, to shortly raise the tariffs to Australia by 9d. per word, so as to diminish the losses arising from the guarantee arrangement, which amounted to over £55,000 during the first year of the experimental tariff. Personally, your Directors would have preferred continuing the 4s. tariff a little longer, in order that it might have been fairly tested, but as the Colonies are suffering from severe commercial depression, and intimated that unless the tariffs were increased they might have to cancel the guarantee at the end of the second year, we had no alternative but to acquiesce in their views. This is the first time, gentlemen, in my recollection when a Government has asked us to put up the tariff. We have generally been pressed on all sides, not only by Governments, but by commercial bodies, to reduce the rates. When negotiating with the Colonies I urged them very strongly to make the rate 5s. instead of 4s., believing that such a large reduction as from 9s. 4d. to 5s. would meet the requirements of the telegraphing public, and give the Company nearly as much money as they were getting at the higher rate. That is now the view taken by the Colonies themselves, and while, as I have stated, we should have been better pleased to have tried the 4s. rate another year, it is our business to meet the wishes of the Colonies as far as we can in all financial matters, and I hope that the traffic will be as large at 4s. 9d. as it has been at 4s., in which case the loss will be insignificant (applause). The "loss on exchange" had been a source of anxiety for a long time past, and as there appears to be little or no prospect of any permanent improvement in the near future, your Directors are seriously thinking of adjusting the tariffs at the stations affected by the depreciation, so as to collect from the public the full value of the charges to which the Company is entitled. The changes will probably take effect from January 1st next. The working expenses have amounted to £79,281, against £71,476 for the corresponding period of 1891, showing an increase of £7,805, but as the ships' expenses are £9,041 more than for the same period of last year, the expenses over which your Directors have control really show a decrease of £1,236. The usual interim dividends at the rate of 5 per cent. per annum have been distributed for the past half-year amounting to £62,500, and the substantial balance of £70,271 is carried forward. I think you will agree with me that this is a very substantial and satisfactory position to occupy. With regard to the cable operations, a further length of 443 knots of the Rangoon-Penang cable has been picked up during the half-year, making, with the cable previously recovered, a total of 825 knots picked up out of the 855 knots originally laid. Most of the cable was found to be in good condition, and has been valued at £42,324, of which £20,000 has been credited to capital expenditure to replace the amount originally taken from capital towards the cost of the Rangoon cable, and the balance of £22,324 has been credited to the general reserve fund, as shown in the printed accounts. Now, gentlemen, I have often referred to our picked up cable, and I think I have shown you that when a cable that has been down for some years, can be picked up again, and laid elsewhere, we have, after all, a property which we can deal with, and that is a very great deal to say of a submarine telegraph system. Out of the picked up cable a triplicate line, 381 knots in length, has been laid between Penang and Singapore costing £25,974. The Foochow-Shanghai section has also been strengthened during the half-year by the partial renewal and alteration of the line at the mouth of the Yangtsze-Kiang river, where interruptions from ships' anchors were becoming frequent. The cost of the operation amounted to £5,307, and with the cost of the triplicate Penang-Singapore cable has been charged to the general reserve fund, which now stands at £426,642, after having expended £1,162,694 out of revenue on cable renewals, duplications, &c., since the formation of the Company (cheers). In other words, we have, without increasing our capital, practically doubled the carrying capacity of your system, besides largely adding to our reserve power by adopting the duplex system of working. The contract for the laying of a submarine cable between Acheen and the Company's system at Sumatra on account of the Netherlands-Indian Government has been successfully carried out and the line opened for traffic. The cost of the work has, of course, been defrayed by the Government, and the line will, I hope, eventually become an important feeder to our system. For some years we have not been as friendly in our relations with New Zealand as we should have liked, although we did everything in our power to conciliate the authorities. We duplicated their cable, and fully met the requirements of the telegraph service, but somehow or other in the Colonies strong ideas prevail of their own power and resources, and they have not always recognised the benefits conferred upon them by having been brought into such close contact with the mother country, and when New Zealand intimated that she would put down a cable for herself, we thought it was very hard, and took measures that we thought we were entitled to take, to protect the Company's interests, with the result that our relations are now perfectly satisfactory with that Colony. (Applause). The Government has done not only what we asked them in fairness to do, but they have joined the general federation of the other Colonies in taking part in this reduction of tariff, which has been so beneficial to the latter. Consequently, the tariff between Europe and New Zealand will be reduced from 10s. 2d. to 5s. 2d. per word for ordinary telegrams, and the following reductions will be made over the New Zealand cables, viz.:—For intercolonial messages, from 8s. 6d. to 2s. per ten words; for international messages, from 1s. to 3d. per word, the Government guaranteeing the Company against three-fourths risk of any loss that may arise from the reductions, and the Company bearing one-fourth. The value of the traffic in question is £26,258, and the Company's risk £4,386 if no increase of traffic results. But with 50 per cent. increase, which would not be an excessive estimate for such substantial reductions, the Company's liability would be only £3,297. The date for bringing the new tariffs into force has not yet been definitely settled, but it will probably be December 1st next. For the last 20 years our relations with Queensland have been rather strained, the Government having endeavoured to thwart us in every possible way. They are now enjoying all the benefits of our enormous system of telegraphy, and the amount that the Government would have to pay to participate in the reduced tariffs which the others enjoy would be less than £1,000 a year, a sum so insignificant that I can only

Hosted by Google

say, with such very distinguished and able men at the head of affairs—Sir Thomas McIlwraith and Sir Samuel Griffith—I am surprised that they have not adopted a more enlightened policy. This unsatisfactory state of things is due to the fact that, in the early days, we did not give Queensland direct cable communication. Hence, there has been an antagonistic feeling to us ever since. The Government want low rates, but unfortunately they don't wish to put their hands in their pockets to the extent of the insignificant sum I have mentioned. The merchants in London recently approached one of the Ministers here—the Hon. W. Wilson—and urged upon him the desirability of getting his Government to join the other Colonies, but so far nothing has resulted from their representations. The Company have also endeavoured in every possible way to conciliate Queensland and get her to become a party to what I may call a moderate agreement. The result of our last appeal is conveyed by the following telegram from the Company's manager at Melbourne, namely :—

"Member of Queensland Parliament, in referring to cable charges, said that inferior position Queensland held in relation to other Colonies was prejudicial to Colony. Thought she should be on same footing, and increased expenditure would be advisable to remove present disabilities.

"Postmaster replied that Government would not join any agreement which would give assistance to monopoly. Government had made agreement with another Company for cable to New Caledonia, and thought they would be defeating their own object by helping to pay subsidy to present Company.

"Matter allowed to drop."

I believe they have agreed to pay £2,000 a year towards it, but that the Company is simply a myth. Whether or no such a small amount is only a drop in the ocean, so far as a Pacific cable is concerned, we cannot see how it will be beneficial to them. Altogether, I have come to the conclusion that if the Government drop that small paltry policy which they are pursuing against this Company, they would very largely benefit the interests of the Colony, and I am not without hope that this will eventually be insisted upon (hear, hear), and the sooner the better. I think, gentlemen, that is pretty much all that I have to say to you to-day. I have given you every possible information on the different points of interest to you. We have had some little trouble, but we have also had successes, and I think, putting the one against the other, I doubt whether I have ever been able to submit to you a more satisfactory statement than I have to-day (applause). I therefore move :—

"*That the report and accounts of the Directors, now submitted, be received and adopted.*"

Mr. F. A. BEVAN seconded the resolution, which was unanimously adopted without discussion.

The CHAIRMAN having intimated that this concluded the business,

Mr. JOHN NEWTON, in proposing a vote of thanks to the Chairman and Directors, wished to emphasise the observations of the former in respect to the portion of the Rangoon-Penang cable which had been picked up and again utilised. He thought that this was one of the most convincing evidences of the valuable character of the property in which they had invested. He also wished to add a word of congratulation to Lord Tweeddale in escaping any injury from the Thirsk collision (applause).

Mr. GIVENS having seconded the motion, it was cordially passed.

The CHAIRMAN said : In returning thanks for your continued support of those on this side of the table, I may tell you that at the present time the depression in our Colonies is very marked indeed, and when we are able, even with all this depression of trade, and in the face of a scarcity of money there, to show such grand results, I think we ought to be very satisfied indeed (cheers). Mercantile men in the Colonies are obliged to button up their pockets, while others have little left to button up. But all this is periodically rectified by "booms," which we see come round from time to time bringing with them returning prosperity. I have been talking recently with men from Queensland, and they tell me that though property has fallen there to the extent of something like 50 per cent., they do not at all despair, believing that the future is bright and full of promise. All that they want is a little time to recover themselves, and then they will go ahead again till another period of over-speculation comes about. But in the midst of this depression, gentlemen, when we continue to pay you the dividend we are paying and carry forward the handsome sum we do to-day, I think we have every reason to congratulate ourselves (applause). I thank you very much for your presence here to-day, and for your unanimous support, as well as for your approval of the report that I have laid before you.

The proceedings then terminated.

Monte Video Telephone Company (Limited).

The annual ordinary general meeting of this Company was held at the offices of the Company, 96, Gresham-house, Old Broad-street, E.C., on Monday last. Mr. Herbert Ward presided.

The SECRETARY (Mr. E. M. Reiss) read the notice calling the meeting, and the report and statement of accounts were taken as read.

The CHAIRMAN said : Gentlemen, with reference to the second paragraph of this report I would call your attention to the fact that during our last business year, ended July 31st last, we have realised an increase of profit over the previous year equal to about 1½ per cent. on our preference share capital. This profit, I must explain, is entirely due to economy in management. Shareholders will observe that Mr. E. F. Powers has resigned the post of Managing Director, which results in a saving of considerable importance. The London expenses have now been reduced to their lowest, and it is the earnest desire of the Board, particularly at the present period, to strengthen the Company in every possible manner in Monte Video, in order to ensure sufficient service, prompt attention, and economy. We have adopted a new plan in connection with the payment of our *employés* who answer the telephone call bells. By this new system we pay each person according to the number of calls answered, so that each assistant receives pay according to the work done. By this means it will be apparent that the attentive *employés* receive a greater percentage of salary than the inattentive. The natural consequence is that all our assistants are constantly on the alert. This system serves to give each one a personal interest in the Company's success. Should it be possible in Monte Video to make any further reduction compatible with efficient management and efficient maintenance of plant, I shall spare no effort to do so, although, at the same time, I must frankly say that in my opinion the expenses have reached the minimum. I next come to the purchase of the Central offices in Monte Video. An explicit account of the circumstances by which we effected this purchase will be found in the third paragraph of the report. I can only assure you that this step has been taken only after the most mature consideration. Here will be found the gist of our financial situation. We have earned a dividend, but we have expended the money in purchasing our central offices. Latest advices received from Monte Video inform us that the lower portion of the premises has been let for £254 per annum. Last April I took the opportunity of visiting Monte Video in order to examine the condition and general management of the Company. I visited all the district offices and interviewed our general manager upon all matters affecting the general working and welfare of the Company and its property. As the result of my investigations, I am glad to be able to report most favourably upon the orderly management that prevailed, and also upon the condition of the Company's property. As most shareholders are doubtless aware, affairs in Monte Video had been and still are in a very unsatisfactory condition, and bearing this in mind I think the shareholders ought to be well satisfied with the report we present. If we continue to do as well in proportion when prospects in Uruguay brighten our position will be a highly satisfactory one. It is the affirmed object of the Directors to present the shareholders very soon with a sound six per cent. paying stock, which, indeed, we hope will be assured at the next yearly meeting. I beg to move the adoption of the report and accounts.

Mr. C. H. SANFORD seconded the motion.

Mr. PRAED asked what was the nature of the negotiations which led up to the purchase of the central offices in Monte Video, and said that he thought that some scheme should be devised by which the preference shareholders should get their interest.

Mr. SANFORD said that he had been very much opposed to the purchase of the building in question, and the Directors had tried to get the owner to continue the lease until such time as they could see their way to get the purchase money. In the first instance they tried to raise money on debentures ; but that could have been possible only at a great sacrifice. The negotiations went on for six months, and eventually the proprietor intimated that they must either purchase the property at once or remove. They could not adopt the latter alternative because it would have been detrimental to the interests of the Company. Hence the reason for making the purchase, the money for which was payable by monthly instalments, terminating on the 2nd of February, 1893, when the Central station would become the freehold property of the Company.

Mr. LOCK, while congratulating the Company on the increased profit earned, thought that the revenue ought not to be diverted from its proper purpose, and while the shareholders would have no objection to lend the Company the money realised by their trade, they should get some acknowledgment for it in the shape of deferred warrants.

After some further discussion to the same effect, the report and accounts were adopted subject to the following rider, proposed by the CHAIRMAN and seconded by Mr. PRAED :—

"*That a dividend at the rate of 3 per cent. per annum be declared on the Preference Shares of the Company, such dividend to be not immediately payable, and that a Committee be formed to agree with the Directors as to the best way of carrying out or securing the payment thereof.*"

The following gentlemen were then constituted the Committee :—Messrs. Praed, Lock, Touch, and Killik.

The CHAIRMAN moved the re-election of Mr. Sanford as a Director of the Company.

Mr. JONES seconded the motion, which was agreed to *nem. con.*

On the motion of Mr. PRAED, seconded by Mr. RATHBONE, the auditors, Messrs. Gerard, Van de Linde and Son were unanimously re-appointed.

Mr. TOUCH proposed a hearty vote of thanks to the Chairman and his colleagues on the Board for their conduct of the Company's business and for the kindly spirit in which they had met the wishes of the shareholders.

A SHAREHOLDER seconded the motion, which was passed, and

The CHAIRMAN having expressed his acknowledgment, the proceedings terminated.

Western and Brazilian Telegraph Company (Limited).

The following is the report of the Directors to be presented at the twenty-fourth ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., on Thursday next, the 10th inst., at 12 noon :—

The total earnings for the half-year ended June 30th amount to £84,021 16s. 9d., as against £104,962. 9s. 7d., a decrease of £20,940. 12s. 10d. compared with the half-year to June 30, 1891. The working expenses amount to £39,140. 16s. 8d., as against £38,638. 10s., an increase of £502. 6s. 8d. Including the amount brought forward from 1891 (£4,486. 18s. 2d.), the balance to the credit of the revenue account is £49,367. 18s. 3d., from which has to be deducted £12,489. 10s. for deben-

Hosted by Google

ture interest, and £6,610. 10s. for the debenture redemption fund, leaving £30,267. 18s. 3d., of which £14,000 has been placed to the reserve fund. This leaves £16,267. 18s. 3d. The Directors recommend the payment of a dividend of 3s. per share, free of income-tax, on the ordinary shares for the half-year, being at the rate of £2 per cent. per annum, carrying forward £1,662. 5s. 3d. The shareholders will note that the falling off in the dividend is mainly attributable to the heavy loss on exchange, which, for the period of which the accounts treat, averaged 11½d. per milreis, as against 18d. for the corresponding period of 1891.

The duplication of the cables between Santos and Chuy has been successfully carried out by the Telegraph Construction and Maintenance Company (Limited), thus duplicating the system throughout between Pernambuco and the River Plate. The cables have also been duplexed between Pernambuco, Rio Janeiro and Santos, and a contract has been entered into and is now in course of completion, the materials being on the spot, for the extension of the duplex system to Monte Video. It will be seen from the above that the Company will shortly have the duplicated line duplexed throughout the entire length of its main system, viz., from Pernambuco to the River Plate.

The competitive cable projected between Senegal and Pernambuco, Brazil, has now been laid.

Since the last meeting the Pacific and European Telegraph Company, the object of which was then fully explained, has been formed, and the erection of the lines between Buenos Ayres and Valparaiso is being actively pushed forward and approaches completion.

The s.s. "Viking," after a service of nine years, was brought home for a new boiler and general repairs, and has left for the coast. The building of the new steamer progresses satisfactorily.

The dividend warrants will be posted on November 11th.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

ALKALI SYNDICATE (LIMITED).—This Company was registered on October 26th, with a capital of £20,000, in £5 shares, to carry on the business of alkali manufacturers, and of the plant, machinery, and materials necessary for such manufacture; to acquire, develop, and turn to account patents, particulars of which are not given, and to carry on the business of civil, mechanical, and electrical engineers.

DOMINION ELECTRICAL COMPANY (LIMITED).—This Company was registered on October 29th, with a capital of £25,125, divided into 5,000 ordinary shares of £5 each, and 500 founders' shares of 5s. each. The objects are to carry on the businesses of telephone, telegraph, and electric light, heat, and power companies in all or any of their respective branches; to acquire, establish, work, manage, control, and regulate works and conveniences for the supply of electric light, heat, and motive power, and for the transmission of telegraphic and telephonic communications; to construct, maintain, lay down, carry out, manufacture, sell, work, let on hire, and deal in telephones, cables, wires, lines, accumulators, meters, lamps, &c.; and to carry on the business of electricians, electrical contractors, electrical and mechanical engineers, suppliers of electricity, and manufacturers of, and dealers in, all kinds of apparatus and things required for or capable of being used in connection with the generation, accumulation, supply, distribution, and utilisation of electricity. The subscribers are:—

	Shares.
Thomas A. Kerr, Tregarthen, Upper Norwood	1
William R. Morton, 12, Whiteley-road, Gipsy Hill, S.E.	1
John F. Lea, Saxonhurst, Fox Hill, Upper Norwood, S.E.	1
George A. Kerr, Woodside, Upper Norwood, electrician	1
Ernest A. Horne, 1, Harvey-terrace, Harvey-road, Leytonstone	1
Herbert T. Sayle, 57, Arlingford-road, Brixton, S.W.	1
William B. Campbell, 61, Farquhar-road, Upper Norwood, S.E.	1

The number of Directors is to be five, the first to be appointed by the above-named signatories.

JULIUS SAX AND CO. (LIMITED).—This Company was registered on October 28th, with a capital of £20,000, in £10 shares. The objects are to acquire and take over as a going concern the business of Julius Sax and Co., carried on by Messrs. Alfred Sax and Charles W. Sax; to carry on the business of supplying electricity in all its branches; to construct, lay down, establish, fix and carry out all necessary cables, wires, lines, accumulators, lamps and works; to generate, accumulate, distribute and supply electricity; and to carry on the business of electricians, electrical and general contractors, mechanical engineers, suppliers of electricity for all purposes, and manufacturers of, and dealers in, all apparatus and things required for or capable of being used in connection with the generation, accumulation, supply, distribution, and utilisation of electricity. The subscribers are:—

	Shares.
John Martin, Mornington-road, Woodford	1
Arthur G. Hales, Somerset-road, Tottenham	1
Frederick Blackhall, 139, Antill-road, Tottenham	1
Charles Keick, 4, Hope Villas, Henslow-road, S.E.	1
W. E. Higgins, Albert Villa, Tower Hamlets road, Forest Gate, E.	1
F. W. Ward, 50A, Trinity-square, S.E.	1
C. F. Young, Courthill-road, Lewisham, S.E.	1

The number of Directors is not to be less than two nor more than five, the first to be appointed by the above named signatories.

NEW BRITISH ELECTRICAL INSTALLATION CONTRACTORS (LIMITED).—This Company was registered on October 28th, with a capital of £25,000, in £5 shares. The objects are to acquire, take over as a going concern, carry on, develop, and extend the business carried on at Worcester by the British Electrical Installation Contractors (Limited), with a view thereto to enter into and carry into effect an agreement to be made with the said Company; to construct, execute, lay down, fix, maintain, and repair engines, dynamos, mains, wires, cables, accumulators, &c., and to carry on the business of electricians, electrical contractors, electrical and mechanical engineers, suppliers of electricity, and manufacturers of, and dealers in, all apparatus and things required for or capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity. The subscribers (with one share each) are Samuel T. Castle, A. Hill Parker, J. S. Cook, Robert J. Surman, Alfred Usher, William H. Walter, and James Duce, all of Worcester. The number of Directors is not to be less than three nor more than five, the first to be appointed by the above-named signatories.

MISCELLANEOUS.—J. DUNNELL GARRETT AND CO. (LIMITED), iron-founders, mechanical, and electrical engineers, &c.; capital £3,000, in £1 shares.——MASBRO' FOUNDRY COMPANY (LIMITED), electrical and mechanical engineers, ironfounders, &c.; capital £10,000, in £10 shares.

BABCOCK AND WILCOX (LIMITED).—The annual return of this Company made up to October 4th, was filed on the 6th. The Company was registered with a capital of £240,000, divided into 10,000 preference and 14,000 ordinary shares of £10 each. At the time of making up, all the shares were taken up, of which 7,999 have been issued as fully paid. Upon the remainder the full amounts have been called and paid.

ERNEST SCOTT AND MOUNTAIN (LIMITED).—The annual return of this Company, made up to October 19th, was filed on the 20th. The Company was registered on November 17, 1890, with a capital of £70,000, in £10 shares. At the time of making up, 4,653 shares had been taken up, of which 2,200 had been issued as fully paid; upon 1,981 shares £6. 5s. had been called, while upon the remaining 472 shares the full amount had been called, resulting in the payment of £17,099. 10s., leaving £1. 15s. in arrears.

IPSWICH ELECTRICITY SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to October 28, 1891, was filed on October 20, 1892. The Company was registered on June 28, 1890, with a capital of £100, in £1 shares. The return just filed, however, shows that up to October, 1891, the negotiations between the Brush Electrical Engineering Company (Limited) and Messrs. Laurence, Scott, and Co. (Limited) respecting the transfer of the latter Company's Ipswich works to the Ipswich Electricity Supply Company (Limited) were still uncompleted, as only seven shares had been taken up, and no calls had been made.

MATHER AND PLATT (LIMITED).—The statutory return of this Company, made up to September 7th, was filed on the 14th. The Company was registered on May 4, 1892, with a capital of £200,000, in £10 shares. At the time of making up, the shares issued, with £9 paid, were the only ones taken up.

CITY NOTES, &c.

ALUMINIUM COMPANY (LIMITED).—The accounts for the year ended June last show a debit balance of £81,989, as against a debit of £71,049 brought forward from the previous year. The Directors, however, consider the prospects of the Company to be more hopeful, and believe that the current year will see their policy of perseverance justified. Within the last few months Mr. Castner has invented a new electro-chemical process, the test results of which are so encouraging that the Directors have decided to put up plant. They now propose an issue of £12,000 10 per cent. "B" debentures.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended October 31 were £889, as against £802 for the corresponding period of last year, being an increase of £87. The total receipts for half-year amount to £14,272, against £12,973 in the corresponding period of 1891, being an increase of £1,299.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts for the month of October were £3,400, as compared with £3,366 in the corresponding month of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The Company announce that they are prepared to issue to the holders of their Five per Cent. Debentures, redeemable at par in August, 1899, an equal nominal amount of their Registered Perpetual £4 per Cent. Mortgage Debenture Stock in exchange. Full particulars and the necessary forms can be had on application at the Company's office, or at their bankers, Messrs. Glyn, Mills, Currie, and Co., Lombard-street, London, E.C. The option to exchange must be exercised on or before Nov. 15th.——The traffic receipts of the Company for the month of October amounted to £61,069 and to £60,784 in the corresponding period of last year, an increase of £285.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of October amounted to £43,342, and to £42,246 in the corresponding period of 1891, or an increase of £1,096.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—Notice is given in our advertisement columns that on the 14th inst. 328 Five per Cent. First Mortgage Debentures of £100 each will be drawn for payment on January 14th.

GENEVA ELECTRICAL COMPANY.—This Company made a net profit of £5,228 last year, and declare a 5½ per cent. dividend. On May 31, 1892, there were 8,261 lamps supplied, against 6,500 at the same date in 1891.

Hosted by Google

NATIONAL TELEPHONE COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to appoint a settling day in and to grant a quotation to this Company's Third Preference Shares, Nos. 1 to 90,950, and to quote in the Official List a further issue of 6,368 ordinary shares, Nos. 447,435 to 453,812.

REUTER'S TELEGRAM COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to quote a further issue of £1,000 of this Company's shares in the Official List.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Oct. 28, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,099.

WESTERN UNION TELEGRAPH COMPANY.—The Directors have declared a stock dividend of 10 per cent.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts for the two weeks ended October 31st show an increase of £67, as compared with the corresponding period.

INDIA RUBBER, GUTTA PERCHA AND TELEGRAPH WORKS CO.,

LIMITED.

ELECTRICAL ENGINEERS,

AND

INDIA RUBBER AND GUTTA PERCHA MANUFACTURERS.

MANUFACTURERS OF

CABLES, WIRES, INSTRUMENTS, INSULATORS, DYNAMO MACHINES, MOTORS, ARC LAMPS & FITTINGS, BATTERIES, CARBONS, TORPEDO APPARATUS.

SPECIALITY.—Underground Electric Light System for High and Low Tension. The only System which has given complete satisfaction.

Contracts entered into for the Erection and Equipment of Central Lighting Stations, the Lighting of Ships, Factories, Houses, and the Supply of Complete Plant for Electrical Traction and Transmission of Power.

VULCANISED INDIA RUBBER.

HOSE, DRIVING BANDS, STEAM PACKING, WATERPROOF GARMENTS and FABRICS, SHOE SOLES, MATS, VALVES, BRAKE BLOCKS, WHEEL TYRES for CABS, CARRIAGES, BICYCLES, &c. SHEET, WASHERS, BUFFERS, SPRINGS, TUBING, SOLID CORD, FOOTBALL BLADDERS, LAWN TENNIS BALLS. MOULDED GOODS to any Pattern.

EBONITE.

Not affected by Vinegar or Hydrochloric or Acetic Acid.

SPECIALITIES IN EBONITE FOR CHEMICAL WORKS.

INSULATORS, BATTERY CELLS, SPEAKING TUBES, SHEET & ROD, SURGICAL APPLIANCES, PHOTOGRAPHIC ARTICLES, SCREW STOPPERS, PUMPS.

GUTTA PERCHA.

TUBING, BELTING, BUCKETS, BOSSES for FLAX SPINNING, GOLF BALLS, SHEET and TISSUE.

ESTIMATES & PRICE LISTS ON APPLICATION.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 756.—Vol. XXX. FRIDAY, NOVEMBER 11, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6.

NOTES.

Prof. Ewing has recently conducted a set of tests on the Parsons steam turbine, and his report, of which we print an abstract in another column, shows that great improvements have been introduced in the construction and mode of use of this ingenious engine. In 1888 a test at an exhibition gave a consumption of steam of about 60lbs. per electrical horse-power-hour, and although the conditions were very unsatisfactory, the steam turbine was generally supposed to be as wasteful in steam as the majority of rotary engines, while the very high speeds employed were enough to deter many engineers. Under these circumstances, when this engine was being pushed some eighteen months ago, we naturally asked for further information about the steam consumption, but nothing was published until January last, after a series of trials by Prof. Ewing. The results showed that 37lbs. of steam per Board of Trade unit, or in figures more easily understood by engineers, 27·6lbs. per electrical horse-power-hour were used. Our previous attitude had been fully justified by the only tests which were published, but we lost no time in bringing these new figures before our readers on January 8th (*The Electrician*, Vol. XXVIII., p. 255). The use of superheating and other modifications have resulted in a further economy of about 27 per cent., bringing the steam consumption down to less than one-third of the 1888 tests. Prof. Ewing finds that the combination of turbine and dynamo in its present state is eminently fitted for central station use. In so peculiar an engine as this, ordinary modes of construction must be modified, and while the inventor has arrived step by step at an excellent result, steam users must be allowed also to form their opinion by degrees from such tests as those which Prof. Ewing has made, and from accounts of practical experience as regards wear and tear. The intermittent admission of steam seems to be an excellent way of governing this engine, so long as no serious fluctuations in the speed are introduced.

Although the Presidential Address of Dr. J. Hopkinson, which we print in another column, was delivered before a junior society, we have no hesitation in presenting it in full to our readers. No such careful examination of the comparative cost of different systems of electric supply has been made since the A. T. *v.* B. T. battle of 1888. The idea of comparing the cost of maintaining a supply station with steam up, and an engine or two just turning round, for a year, with the same station running at full load continuously from year's end to year's end, is a very bold one, and few men would dare to illustrate a thoroughly commercial Paper by such purely hypothetical cases which can neither occur nor be approached in practice. But the result is of great interest, and the general principles of his argument are so clearly expressed that anyone in possession of figures relating to any particular case may fill them in, and prove for himself the application of this comparison. The conclusions about the use of batteries will of course fail to meet with acceptance in certain quarters, but the object of this Paper was not to teach the young engineer how to design a station.

The system of charging for electrical supply advocated by Dr. Hopkinson is admirable from the supply companies' point of view, but we are inclined to doubt whether it will be popular among consumers. Dr. Hopkinson does not, however, encourage the modest consumer, but offers special advantages to selected customers. There is no trick about this system. It is suggested that a fixed charge be made for the privilege of being able to turn on the light, and that a small charge of say 2d. per unit be made for the actual quantity consumed. This means a "reduction on taking a quantity," but comes to 8d. per unit if the supply is taken for less than 500 hours per annum. This is equivalent to turning on the light at dusk and extinguishing it at 7.30 all the year round, so in the case of shops which close at about this hour the system does not appear to offer much advantage. On the other hand, in residential lighting in which the privilege of switching lights on and off is well appreciated, the whole period from dusk to 11 p.m. is about 1,800 hours. A supply at a given rate for 1,800 hours appears, on Dr. Hopkinson's curve, to be charged at about 3½d. per unit. But in domestic lighting the maximum number of ordinary lamps are lighted for only an hour or two each night, while occasionally a considerable proportion of additional lamps are used. This normal maximum, as well as the occasional maximum, will seriously interfere with the attractive 3½d., and the benefits of this system will be best appreciated by clubs and other establishments in which a constant number of lamps are burned for some 2,000 hours.

The interpretations which Prof. Fitzgerald suggests in our Correspondence Columns to account for the connection between sunspots and magnetic storms are very interesting. M. Ricco in his communication to the Académie des Sciences,

Hosted by Google

which we printed last week, only vaguely suggested that the vast movement and contact of vapours at different temperatures might generate electricity; and that masses of dense iron vapour might be the cause of electric or magnetic action or induction. It is very difficult to imagine an electro-magnetic beam like that of a lighthouse; but as we know that there is a shear in latitude of the sun's surface there might also be a radial shear which would point such a ray backwards. The hypothesis of charged atoms is of much greater interest, and fits well with the phenomena of comets' tails and the rays of the corona, which are known to be associated with sun-spot regions. The earth would take 25 to 30 hours to pass through the cone of 15 degrees or 20 degrees to which Prof. FITZGERALD alludes, and we would again ask for further information as to the rise and fall and general character of a magnetic storm as a whole. M. RICCO endeavours to take only the instant of maximum disturbance. Comets' tails are of a conical shape, but coronal rays appear in photographs to be of a flame-like form. If this is their real outline, perhaps they only lick the earth with their tips. It has been on more than one occasion suggested that convection currents in the atmosphere may form the "return circuit" of earth currents existing on the earth's surface; but Prof. FITZGERALD is, we believe, the first to suggest the possibility of such currents existing between the sun and the earth. The amount of matter needed to carry the atomic charges turns out to be surprisingly small.

ONE of the most striking advantages of the electric welding processes, both of ELIHU THOMSON and BENARDOS, is the absence of scale and oxidisation. Electric forging has been suggested, and the tempering of springs by electrical heating is a well-established operation. One of the latest applications of an electric current to metal working is the production of ornamental twisted bars, instead of heating these in a forge in the usual way. Any portion of a bar can be heated by means of a current passing between clamps, and the requisite twist can be applied by a crank. The amount of twisting may thus be regulated to a nicety. The work can be done very rapidly and is of course free from scale and oxidisation.

ANOTHER of the numerous legends with regard to intense and wide-reaching disturbances due to the presence of magnetic rocks has been exploded by measurements recently made on board the French research steamer "La Manche," which has been cruising about during the past summer in the neighbourhood of Spitzbergen, Iceland, and Jan Mayen Island. In a Paper presented to the Académie des Sciences, at its last meeting, Commander BIENAIMÉ says, "The truth is that the horizontal component, diminishing rapidly as one approaches the Pole, local influences cause a very sensible effect on the compass which one has to take note of all the more because the dial is a long time in again assuming the position of equilibrium from which it has been deflected." Nevertheless, observations made on land at Reykjavick, under the best conditions, never gave a larger disturbance than 2 deg. or 3 deg., whilst at sea the phenomenon was quite negligible.

THIS result is in complete accordance with those obtained by Profs. RÜCKER and THORPE in their magnetic survey of the United Kingdom, and with the phenomena observed by H.M.S. "Penguin" in the Pacific. Writing to *The Times* with reference to the opinion generally entertained at the time that the loss of H.M.S. "Serpent" off Cape Finisterre just two years ago was due in some way to the malign influence of magnetic rocks, Profs. RÜCKER and THORPE showed the extreme improbability of the hypothesis, and instanced Compass Hill, Canna Island, which, although powerfully magnetic, has no appreciable influence on a compass 200 yards from its base. Almost at the very moment that this letter was being penned some observations were being made by H.M.S. "Penguin," off Bezout Island, North-West Australia, which confirmed this view in a still more remarkable manner.

ON November 6th, 1890, the "Penguin" being two miles north of Bezout Island, a deflection of 22 deg. was observed. The ship was immediately anchored and the matter investigated. On the island itself the magnetic elements were found to be normal. But 2·14 miles to the north the S. dip varied by 33 deg., but became normal again within a few hundred yards in any direction. At the centre of the disturbance the *deflection* was nearly normal, but 100 feet to the south it was 55 deg., the compass being more or less affected over an area of about one square mile. The notion that ships' compasses may be disturbed out of sight of land by magnetic rocks on or near land, may now surely be relegated to the realms of scientific myth.

PROF. TILDEN'S letter to *The Times* on scientific titles, to which we briefly alluded last week, has called forth only one reply. In this, the writer unconsciously exemplifies the confusion which is daily increasing between education and knowledge. Because a University graduate "might well be excused from replying" if any one were to "suddenly question him in Greek, or even Latin," or if required "to solve a Cambridge problem in the higher mathematics," it is suggested that a University degree may "be in some sense a bogus title." All the miscellaneous information which is imparted by technical colleges is called education, and because it has a high utilitarian importance it is assumed to be of great educational value. Teach a lad how to set a slide valve, intelligently of course, and after any elementary acquaintance with the steam engine, and as long as he remembers, he knows something useful, and is able to perform this useful operation. If he forgets it he loses ground to that extent. But teach him the fifth proposition of Euclid, after a grounding in the first four, and whether he forgets them or no, is of little importance, they have no more utilitarian value than Greek. Education consists in learning and in appreciating, not in retaining the knowledge. An educated man may degenerate, say after spending thirty years in the Australian bush, but broadly speaking, the faculties which are developed by true education remain in readiness for attacking the problems of after life.

Hosted by Google

Wycombe.—The Town Council has decided to apply for an Electric Lighting Provisional Order.

Telephones in Denmark.—The Danish Government, it is stated, has decided to take over the telephones.

Poplar.—The Poplar District Board of Works have intimated their intention of applying for an Electric Lighting Provisional Order.

Royal Holloway College.—The Governors of this college have appointed Mr. H. L. Callendar, Fellow of Trinity College, Cambridge, to the professorship of physics.

Sir John Pender.—The King of Portugal has conferred upon Sir John Pender the Grand Cross of the Most Distinguished Order of Nossa Senhora do Conceicao de Villa Vicosa.

The Stranding of H.M.S. "Howe."—Reports from Ferrol state that the lightening operations connected with H.M.S. "Howe" are being much facilitated by the electric light from H.M.S. "Rodney."

Fareham.—The Directors of the Fareham Electric Lighting Company have given notice to their customers that from the 1st inst. they will supply the light by meter only, at a fixed rate of 8d. per unit.

Antwerp.—The agreement between the Antwerp Municipality and M. Van Rysselberghe with regard to electric lighting and distribution of power was signed last week. The work will be commenced at once.

Glasgow University Physical Society.—At the first ordinary meeting for the Session of this Society, the President, Mr. James H. Gray, delivered an inaugural address on "The Electro-Magnetic Theory of Light."

Bristol.—On Wednesday last, on behalf of the Electrical Committee, there was a motion to add to the area of supply under the Electric Lighting Order, 1883, the area included in Schedule B. This practically means the whole of the city.

Proposed Electric Railway for Barry Island.—At a special meeting of the Directors of the Barry Railway Company, held on Wednesday last week, the scheme for the construction of an electric railway to Barry Island was discussed, and it is expected the work will be taken in hand forthwith.

Electrical Trades' Union.—In connection with the Glasgow branch of this Union, Mr. H. A. Mavor (of Messrs. Mavor and Coulson) delivered the first of a course of six lectures on Friday evening last at the St. Andrew's Hall, Glasgow, the chair being taken (in the absence of Lord Kelvin) by Mr. Wm. M'Whirter. There was a large attendance.

Belfast.—At the meeting of the Town Council on the 1st inst., Alderman Johnstone proposed that the minutes of the meeting of the Council in Committee of October 13th, so far as they referred to the question of electric lighting, should be confirmed. An amendment in favour of a 50,000-light plant as against the proposed 10,000-light plant was defeated by 21 votes to 7, and the original motion passed.

Paisley.—At the last meeting of the Town Council it was stated that the Electric Lighting Committee had not seen their way to recommend the Council to proceed with the laying down of an installation for the electric lighting of the town under the Order obtained last year, the probable demand for the light not being sufficient to warrant the expenditure involved. It was remitted to the Electric Lighting Committee to consider and report what they would advise to be done, as the Order expires in July next.

Liverpool Overhead Railway.—The first train was run on this railway on Tuesday last, carrying the Directors and their friends. The trip was satisfactory, the behaviour of the generating engines and dynamos being all that was anticipated. There were present the Chairman of the Railway Company, Sir William Forwood, and the whole of the Directors; Mr. J. H. Greathead and Mr. Francis Fox, the engineers. The contractors, the Electric Construction Corporation, were represented by Mr. Thomas Parker.

Obituary.—The death is announced, on the 30th ult., of Dr. L. Loewenherz, Director of the technical division of the Physikalisch-Technischer Reichsanstalt.——The death is also announced, at Blenheim Palace, at the age of 48, of the Duke of Marlborough, who, after having long taken considerable interest in electricity, and contributed several popular articles on its applications to various magazines, became within the last few years prominently connected with electrical company promotion. The deceased was Chairman of the Brush Electrical Engineering Company, the New Telephone Company, and the Electric and General Investment Company, and a Director of the City of London Electric Lighting Company.

Royal Society.—The following is a list of names recommended by the President and Council for election into the Council for the year 1893, at the anniversary meeting on November 30th:—President, Lord Kelvin; treasurer, Sir John Evans; secretaries, Prof. Michael Foster and Lord Rayleigh; foreign secretary, Sir Archibald Geikie; other members of the Council, Captain W. de W. Abney, Sir Benjamin Baker, Prof. Isaac Bayley Balfour, W. T. Blandford, Prof. Carey Foster, R. T. Glazebrook, F. Duncane Godman, Prof. John Hopkinson, Prof. J. Norman Lockyer, Prof. J. G. M'Kendrick, W. D. Niven, W. H. Perkin, Rev. Prof. B. Price, the Marquis of Salisbury, Adam Sedgwick, and Prof. W. A. Tilden.

The Plymouth Tramways and Electric Traction.—At Wednesday's meeting of the Plymouth County Council the Works Committee presented a report by Mr. J. Clifton Robinson as to the present position and future prospects of the tramways recently purchased by the Corporation. The report concludes with a strong recommendation in favour of the adoption of electric traction, at a total estimated cost of £50,000. Mr. Robinson estimates that the earnings of eight cars, running 80 miles a day, at a cost of a shilling per mile run, would be £11,680 per annum. The annual cost of working is set down at £7,800; and in this sum Mr. Robinson has included nearly £2,000 on account of sinking fund. There would thus be a credit balance of £3,800, equal to 7½ per cent. on the total capital outlay.

Society of Arts.—The first meeting of the 1892-93 Session of the Society will be held on Wednesday, November 16th, when the opening address will be delivered by Sir Richard Webster, Q.C., M.P., Chairman of the Council. Previous to Christmas there will be four ordinary meetings, in addition to the opening meeting. A Paper will be read in the course of the Session by Prof. George Forbes on "The Utilisation of Niagara." Cantor lectures will be delivered by Prof. Vivian Lewes on "The Generation of Light from Coal Gas, and its Measurement," on November 21st, 28th, December 5th, 12th; by Dr. J. A. Fleming on "The Practical Measurement of Alternating Electric Currents," on January 30th, February 6th, 13th, 20th; and by Prof. W. Chandler Roberts-Austen, on "Alloys," on March 6th, 13th, 20th.

The Smoke Nuisance in Boston.—The Boston (U.S.A.) electric light and traction companies are much exercised over a recent ordinance of the municipality, laying down that "No person shall use bituminous coal for the purpose of generating steam in boilers in any building, unless the furnace in which the coal is burned is provided with some effectual device for consuming its own smoke." Upon this the inspector of buildings ruled that a smoke-consuming device, in order to be approved, must consume at least 90 per cent. of the smoke emitted. Up to the present no device has been forthcoming fulfilling these requirements, and the authorities have suspended the enforcement of the ordinance during such time as may be necessary to allow the inspector to investigate and report upon the merits of devices on the market. If no smoke annihilator is discovered, and the ordinance comes into force, it will mean an addition of £4,000 a year to the coal bill of the Boston Electric Light Company alone. The local Edison Company is said to use about 44 tons, and the Boston Company about 49 tons of soft coal per diem.

Royal Institution.—At the general monthly meeting of this Institution on Monday last, the special thanks of the members were returned to Mr. Thomas G. Hodgkins, of Brambletye Farm, Setauket, Long Island, New York, for his most valuable gift of $100,000 (£20,523 6s. 11d.) The special thanks of the members were returned to the Goldsmiths' Company for their generous grant of £1,000 "for the continuation and development of the valuable original research which the Society is engaged in carrying on; and especially for the prosecution of investigations on the properties of matter at temperatures

Hosted by Google

approaching that of the zero of absolute temperature." The special thanks of the members were returned for the following donation:—Mr. F. D. Mocatta £50, for carrying on investigations on liquid oxygen.

Carlow.—The Gas *v.* Electric Light question came before the last Carlow Quarter Sessions. Several householders having substituted electricity for gas, continued to hold on to the meters, so as to be able to fall back upon the gas in case of a failure in the electric supply. At the last session the Gas Company brought an action against such a householder to compel him to give up the meter, as it was the property of the Company. The County Court Judge, without deciding the question that had been raised as to the right or wrong of the Company refusing gas to the private consumer when he pays for what the meter registers, dismissed the case on the ground that the Company had no right to remove the meter until they had first cut off the connection with their mains.

Opposition to the Overhead Trolley System in New York.—Alluding in a recent leading article to the prejudiced opposition of the New York daily press to the introduction of the trolley system, our New York contemporary the *Electrical Engineer* delivers itself as follows:—"According to the Mohammedan faith the day of judgment has three periods, each of which is heralded with a blast. The first of the blasts is Consternation, to which succeeds Examination, the final one being that of Resurrection. Our New York papers have fired off their blast of Consternation about the trolley in magnificent style. The skill shown by some of them in blowing their own trumpet has come in very handily. Just now we are being treated to the blast of Examination, from which good results may be expected; and then, later on, we shall see a change of heart, when our contemporaries will rise on the stepping-stones of their old ignorance to higher things, and come to acknowledge in the hour of intellectual Resurrection that the Trolley, equally with the Newspaper, makes for public welfare."

Old Students' Association.—The annual dinner of this Association was held at the Holborn Restaurant on Oct. 28th. The report, which was read by the honorary secretary, showed that the Association is in a very satisfactory condition, both as regards the number of members, and as to its finances. In the course of the speeches which alternated with some excellent music, Mr. Mordey, in proposing "The City and Guilds of London Institute," observed that Prof. Ayrton had the whole world for his class. Prof. Ayrton made a most amusing reply, saying that he had received a threat that if he didn't make a speech, the Secretary would discover an entirely new theory of magnetism. Mr. H. C. Saunders, Q.C., said that the three colleges of the City and Guilds of London held a unique position which was very gratifying to the governing body whom he represented. Mr. Esson, the retiring president, announced that the ballot for officers for the next year had resulted in the election of Mr. Ll. B. Atkinson as president, and Mr. Vignoles as hon. sec. Mr. Esson alluded to the new president as a "drehstrom sort of man, a good engineer, a good electrician, and one who would be a good president."

"Industries."—Our contemporary's special number of last week dealing with the engineering features of the Houses of Parliament was of the exhaustive and exhausting character usually associated with such efforts. On the principle that he "who drives fat oxen should himself be fat," our contemporary argues that a body which has for the past fifty years devoted so much of its valuable time to sanitary legislation, should at least set its own house in order and make it a model of what should be done wherever circumstances permit. It is, therefore, satisfactory to learn that the Houses of Parliament satisfy our contemporary's syllogism. We always understood that our legislators were extremely well off in the matter of fresh air and freedom from noxious fumes, but we did not realise until we perused the very lucid and interesting article which appeared in *Industries* of November 4th what an onerous business the ventilation and sanitation of the Legislature really was. We must congratulate our contemporary on having brought out a thoroughly readable account of an important, but not always interesting, piece of engineering. The illustrations, as all illustrations should, illustrate the text and are no mere pictures.

The Incandescent Lamp in America.—The electric lighting industry in the United States appears, says *Industries*, to be passing through an anxious crisis now that the Edison patent has been upheld. If the General Electric Company adopt the policy of charging comparatively small royalties, of course it will be easy to arrange a scheme of working. The General Electric Company alone have not at present the means of making all the lamps that are required in the United States, so it would be disastrous to have the other factories closed. On the other hand, it may be easy for them to enlarge their output, and perhaps to take over the trained hands from the other lamp works. If they adopt the policy of declining to supply lamps except where their dynamos are used, they may cause a great deal of trouble. On the other hand, the Westinghouse firm profess to have a lamp ready for the market which is no infringement of Edison's patent, and which is much better than the ordinary kind. We have heard of this lamp before. It turned up every one or two weeks in this country when Edison's patent threatened to prove valid. As soon as the monopoly was established by law the improved lamp seemed to find the atmosphere uncongenial, and it has apparently gone over to Pennsylvania for change of air. On the other hand, the Westinghouse firm have a very able staff of electricians, and the improved lamp may really be on the point of coming into existence in America.

Brighton.—We have received a copy of a rather long letter which was addressed by Mr. R. Hammond to the *Daily Telegraph*. Mr. Hammond contends that when a Corporation takes the supply of gas, water, or electric lighting into its own hands, it should take over at a valuation the works of the private company that has hitherto had such supply in its hands. Though the Brighton Electric Supply Works, which were founded in 1881, have carried on electric lighting in Brighton and Hove, the Corporation of Brighton a year ago, says Mr. Hammond, actually started opposition works, and refused to treat with the Brighton and Hove Electric Light Company on any terms whatever for the acquisition of its undertaking. The Company offered to charge the Corporation for the lighting of the sea-front at the same price as gas; but this offer was declined with thanks. The Brighton Electric Light Company has not confined the electric light supply to any particular portion of the town, but has run its wires in every direction, wherever the demand arose, the circuit at one time measuring 20 miles. The Corporation, which obtained Parliamentary powers as far back as 1883, neglected to do any work whatever. The engineers followed the then universal custom of placing the cables overhead; but in 1888 the Company made application for a Provisional Order to place its cables underground. The Corporation, however, not consenting to the granting of the Order, the Board of Trade held a local inquiry in April, 1889. The Corporation opposed the grant of the Order to the Company upon the grounds that electric lighting was in an experimental stage; that no system was reliable; and that when such was discovered the Corporation intended to supply the light themselves, under the Order which had been granted to them, and which, up to the date of the inquiry, and indeed till July, 1889, had been a dead letter. The inspector reported in favour of an Order being granted to the Company for Brighton, but the Corporation sent a deputation to the Board of Trade to assure the President of their intention to carry out the provisions of their Order upon which the Company was refused the Order which they had been invited to apply for. The Corporation applied to the Local Government Board for sanction to borrow some £30,000. The proposed expenditure by the Corporation was sanctioned, and the Corporation works erected. The Town Council confidently expected that the opening of the works a year ago would result in the immediate ruin of the Company; but, continues Mr. Hammond, the Company has gallantly held its ground, beating the Corporation at every point, and actually doubling its business during the past twelve months. As this letter was not published by the *Daily Telegraph*, we have pleasure in laying the main facts before our readers.

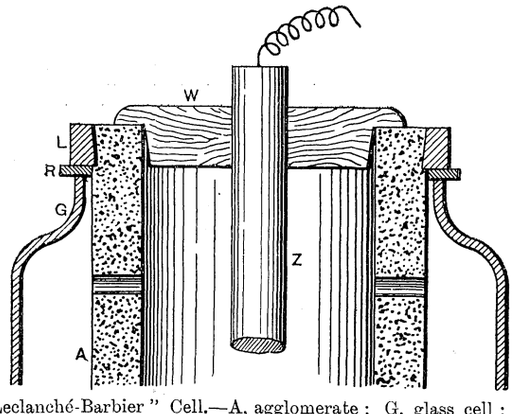
IMPROVEMENTS IN THE LECLANCHÉ BATTERY.

Peroxide of manganese was first used in a voltaic battery, we believe, by De La Rive, but numerous difficulties presented themselves in practice, and it was not until the late M. Leclanché, of the Eastern Railway of France, combined the peroxide with crushed carbon, and packed the mixture in a porous pot, that this type of cell came into common use. Since 1866 a number of modifications have been made, some have been improvements, but others have been of doubtful value. M. Leclanché's brother introduced the agglomerate block, which dispensed with the porous pot, thus lowering the internal resistance. The most elaborated form of this type is the six-block agglomerate cell which is largely used by the Post Office. Here six rods of agglomerate are bound to a grooved carbon block by sackcloth and rubber bands. A sheet zinc cylinder surrounds the negative element, thus bringing the resistance down to about 0·2 ohm. A retrogression in a somewhat important point may here be noticed. The old Leclanché battery could be easily sealed up, small vent holes being provided either by glass tubes or by short pieces of cane. The porous pot was almost always sealed thus, and the whole cell is often covered in the same way with pitch. But the agglomerate blocks did not afford such facilities for sealing, and in the six-block pattern no provision is made, in many cases, for retarding evaporation. A modification of the Leclanché battery has been made by Lacombe & Co., who use a cylindrical shell of carbon resting on a china or glass ring. Within this a perforated china cylinder is set, and the space between was filled with crushed carbon and peroxide of manganese. A cover, in which



The "Leclanché-Barbier" Cell.—A, agglomerate; G, glass cell; L, lead collar; R, rubber ring; W, wood plug; Z, zinc.

the zinc rod is fixed, rests on the cylinders. It is claimed that a very perfect chemical action takes place, because the depolariser forms a continuous sheet between the zinc and the carbon, and the hydrogen must, therefore, traverse the whole thickness. The cylinders stand a little higher than the top of the glass jar, leaving a narrow gap through which evaporation can take place. The internal resistance of such a cell is lower than that of the old Leclanchés, but we have no information as to the relative resistances of this type and of the best agglomerate Leclanché. We observe that the Lacombe cell is illustrated in Messrs. J. Verity's catalogue.

The latest modification is to be found in the Leclanché-Barbier cell, which is being introduced by Mr. R. Aylmer. The cell consists of a cylinder of carbon and peroxide agglomerate, but the mixture differs in several respects from the well-known blocks of the Silvertown Company. Graphite appears to be used, at all events, on the surface. We are informed that it is active throughout, being thoroughly porous. The distinctive feature in the arrangement of the battery is that this agglomerate cylinder rests not on the bottom of the jar, but on its lip. The upper end of the cylinder is slightly bevelled, and a ring of lead is cast round it, forming an attachment for a terminal and a collar for supporting the cylinder. A rubber ring is placed between this collar and the lip of the jar, thus making a fairly tight joint. The zinc is fixed in a paraffined wooden cover, and is tipped with a piece of rubber, preventing accidental contact with the agglomerate cylinder. This cover enters a little into the cylinder, fitting loosely, and allowing escape of gas, but preventing evaporation. So effective is this sealing that such batteries, as we are informed, have stood for four years without losing more than a millimetre of solution by evaporation. As in the Lacombe cell the agglomerate cylinder is perforated to allow circulation of the solution.

There is a great diversity of opinion, strange to say, as to the best strength of the sal-ammoniac solution for the Leclanché battery. A majority of text-books recommend a saturated solution, but others prescribe two ounces of sal-ammoniac to a pint of water (Allsop), dilution of a saturated solution by one-tenth of its bulk of plain water (Kempe), and even a half-saturated solution (Sprague). The well-known trouble of creeping salts seems to be connected both with the degree of saturation of the excitant, and indirectly with the evaporation of the water. A weaker solution seems only to have been suggested in order to avoid this creeping; but it appears that if an effective sealing is adopted, and if the porous pot is dispensed with, creeping does not occur.

More than one improvement has been suggested in connection with the excitant. It is important that sal-ammoniac should be free from lead and other minerals. We are not inclined to notice secret preparations in these columns, but a special salt for the Leclanché-Barbier battery may be mentioned. We understand that it cannot be used with agglomerate blocks, since it attacks the rubber bands. The advantage which is claimed for it lies in the absence of the insoluble crystals which form round the zinc rods of Leclanché batteries. The zincs are often corroded at the water line, but with this salt they taper off downwards and present a uniform grey surface, with no signs of crystals.

We have received a sample of "Electrogen Traub," another secret preparation. The agents inform us that no incrustation takes place, the zincs wear evenly, and the current is "considerably intensified." We have made inquiries about the strength of solution recommended, but can only learn that 90 grammes suffice for a cell which requires 150 grammes of sal-ammoniac.

The latest form of "dry" battery consists of a thick cylinder of agglomerate, which is surrounded by the zinc, the two elements being separated by a moist conducting cement. The advantage which is claimed over other dry cells consists in the ease with which this cell may be revived when run down or partially dried up. To do this, the hollow in the middle of the cell is merely filled with sal-ammoniac, and allowed to stand for a few hours. For temporary telegraphic work, as at race meetings, where cells are generally charged and the solution thrown away after the work is done, these cells should be very useful, as they can be knocked over, or worked while lying on their sides, without disadvantage. These cells are to be found in the latest list of the Silvertown Company, who originally introduced the Leclanché cell into this country, and are supplied also by Mr. Aylmer.

THE COST OF ELECTRIC SUPPLY.*

BY DR. JOHN HOPKINSON, F.R.S.

The interests of an engineer are many-sided. If he is to successfully use the forces of nature for the service of man he must understand how those forces work; he must, in fact, be scientfic. It may be that his ideas are arranged differently from the ideas of those who study science for its own sake, and without regard to practical applications, but if he is to succeed they must be so arranged that he can deduce from knowledge already acquired, knowledge which is applicable to new cases which have not as yet come under his observation. The engineer who can only do that which he has seen done before may be a practical man, but he will always belong to a lower grade of his profession. The scientific engineer is one who by his knowledge of nature is able to deal with new engineering problems and provide useful solutions of those problems. But a practical man must be something more than a man of science, or rather he must look at matters from a different point of view. He cannot choose some feature of a problem, concentrate all his attention upon that, and leave other matters out of consideration,

* Presidential address delivered November 4th, 1892, before the Junior Engineering Society.

Hosted by Google

which is the process by which most scientific advance has been made; but he must always deal with the whole matter before him and leave no relevant question out. But an engineer may be scientific, inasmuch as he has knowledge of nature and the power of applying that knowledge in new cases; he may be practical in the sense that the means he devises to attain his ends may be complete at all points, and not break down from trifling defects, and yet may find that there are other subjects which he has to consider. Our complete engineer must give his attention to commercial matters as well; he must know if, when he has devised the means to attain the ends in view, those ends when attained will result in a profit. He must recognise the conditions which render an undertaking economical to work, and which secure that it shall bring in a large return. When it has been my lot to address engineers I have usually directed attention to some scientific point which I thought would be of interest to them. This evening I should like to go to the other extreme and deal with a purely commercial question, with a matter into which no science enters, and which relates entirely to pounds, shillings, and pence.

You are all of you familiar with the fact that the expenses of an undertaking may be broadly divided into two classes. On the one hand there are expenses which are quite independent of the extent to which the undertaking is used, and on the other, expenses which are absent unless the undertaking is used, and which increase in proportion to the use. For example, the charges for interest on the construction of a bridge are the same whether that bridge is used much or little or at all, and the cost of maintaining the bridge is also practically independent of its user. The same is true in a large measure of a harbour or a dock. Such undertakings lie at one extreme of the scale. It is less easy to find good examples at the present day of the other extreme, as nearly all undertakings with which engineers have to deal require the employment of some capital, and there will be a fixed charge for the use of that capital and for maintaining against the assaults of time the things in which the capital is embodied. But we can readily see for example in the case of a cotton mill that, if on the one hand there are expenses for interest and dilapidation which are independent of the amount of yarn actually manufactured in a given factory, there are other expenses for material and labour, and even for actual wear of machinery which will be very nearly proportional to the output. Undertakings vary enormously in the proportion of these two classes of expenses, in some the expense is quite independent of the extent of the user, in others it is for the greater part proportional to the user.

But undertakings differ from each other in another respect. In some cases the service which the undertaking is designed to render can be performed at a time selected by the undertaker; in others at a time selected by him to whom the service is rendered. In the case of most manufactures it matters not if the thing made is made to day or to-morrow, in the morning or the evening, for it will not be used for a month hence, perhaps; the thing can in fact be extensively stored and kept till it is wanted. Other services must be rendered at the moment the person served desires. For example, the Metropolitan District Railway must be prepared to bring in its thousands of passengers to the City at the beginning of the day and to take them back in the evening, and for the rest of the day it must be content to be comparatively idle. In this case the services cannot be stored. The line must be of a carrying capacity equal to the greatest demand, and if this be great for a very short time the total return for the day must be small in comparison with the expense of rendering the service. In such a case it would not be inappropriate to charge more for carrying a person in the busy time than in the slack time, for it really costs more to carry him.

Let us see how these considerations apply to the supply of electricity for lighting. Electrical engineers now realise that they have to provide the same plant and no more to give a steady supply day and night as to give a supply for one hour out of the twenty-four. They also now realise that if they are to be ready to give a supply at any moment, they must burn much coal and pay much wages for however short a time the supply is actually taken. Indeed, the term "load factor," proposed by Mr. Crompton, is as constantly in the mouths of those who are interested in the supply of electricity, as volt or ampère or horse-power. The importance of the time during which a supply of electricity is used was so strongly impressed on my mind years ago that in 1883 I had introduced into the Provisional Orders, with which I had to do, a special method of charge intended to secure some approach to proportionality of charge to cost of supply. Unfortunately the orders of that day all came to nought.

A supply of electricity must be delivered at the very moment when the consumer chooses to use it, and as long as and no longer than he pleases to use it; it cannot be very readily or cheaply stored, and much of the cost of production is the fixed charge for plant and conductors. Furthermore, the provisional orders require that the supply shall be available at all hours; hence coal must be consumed, and workmen must attend, though but few consumers are drawing a supply. The service of supplying electricity has, from an economic point of view, a great deal of similarity to the service of providing a breakwater for a harbour. A great deal of the expense is independent of the number of hours in the day during which the supply is used. To put it in another way, the cost of supplying electricity for 1,000 lamps for ten hours is very much less than ten times the cost of supplying the same 1,000 lamps for one hour particularly if it is incumbent on the undertaker to be ready with a supply at any moment that it is required.

The actual importance of considerations of this kind can only be realised by examining figures. The figures may as well be estimated figures, because the circumstances vary from one neighbourhood to another. No criticism of the details of the figures will affect the general character of the conclusion. Let us, then, imagine a station capable of supplying 40,000 16-candle lamps at one time, with mains and spare machinery enough to ensure that the supply shall not fail, and let us see what the charge for running such a station will be; firstly, on the hypothesis that it is always to be ready to supply the 40,000 lights at half-an-hour's notice day or night, but that the lights are hardly ever actually required; secondly, on the hypothesis that the 40,000 lights are steadily and continuously supplied day and night. These are the two extreme cases possible. In the former the load factor is nil; in the latter it is 100 per cent. If the charge is by meter at 8d. per unit, in the former case the revenue will be nil; in the latter it will be £730,000 a year.

We are going to divide the cost of supplying electricity into two parts—a part which is independent of the hours the supply is used, and a part which is directly proportional thereto, and we are going to estimate the amount of each element. It is for the purpose of ascertaining these elements that we consider two quite hypothetical cases—cases which can themselves never actually occur,

We must first have an idea of the capital outlay required. To provide the maximum of 40,000 lamps we need to deliver 2,500 units per hour, and we may estimate the capital outlay as follows:—

Land	£25,000
Buildings	15,000
Boilers and pipes	14,000
Engines	24,000
Dynamos	15,000
Switchboard and instruments	2,000
Feeders and mains	50,000
	£145,000

Let us deal with the annual charge for each item of capital separately on the two hypotheses. The charge for land and for buildings including repairs is clearly the same in the two cases, say at 4 per cent. £1,000 for the land, and at 10 per cent. £1,500 for the buildings. The boilers, engines, and dynamos will have a charge for interest, and a charge for writing off or amortization as the French call it, that is, for writing off the value of the plant before the time at which it becomes antiquated—exactly the same in the two cases. The boilers, too, will require exactly the same repairs whether they are merely keeping steam or whether they are generating steam continuously; but the machinery will certainly require more for repairs and renewals if it is all running than if a part only is running without load and the rest is standing ready for a load if required. I take 4 per cent. as the charge for interest; 3 per cent. for amortization; 8 per cent. for repairs and maintenance. Of the repairs of engines and dynamos I assume that 2 per cent. will be applicable if the plant runs light, the remaining 6 per cent. if it is fully and continuously loaded. The expenses connected with conductors and switchboard, &c., will be exactly the same whether the current is passing or not; these I take at 15 per cent. The rates I put down at £500 a year. The account, then, for the fixed charges already enumerated would stand as follows:—

	Running Light.	Fully Loaded.
Land	£1,000	£1,000
Buildings	1,500	1,500
Rates	500	500
Boilers	2,100	2,100
Switchboard and conductors	7,800	7,800
Engines	2,160	3,600
Dynamos	1,350	2,250
	£16,410	£18,750

We now come to a most important item in the account—the coal. There is no doubt that with uniform and continuous load a unit of electric energy—1⅓ H.P. for one hour—can be produced for less than 3lbs. of coal; it is also pretty much admitted that with a load factor of about 12 per cent., but continuous maintenance of pressure, the consumption of coal in good practice is something like 7lbs.; that is to say, to keep the boilers warm, turn round the

Hosted by Google

machinery for 24 hours, and deliver full current for 24 hours, will require 72lbs. of coal per kilowatt; whereas to keep the boilers warm, turn round the machinery, and deliver current for 3 hours, will require 21lbs. of coal. The boilers being kept warm, it will take 51lbs. of coal to generate steam enough to give a unit per hour for 21 hours; 58lbs. to give a unit per hour for 24 hours; subtracting this from 72lbs., the amount required both to generate steam and keep the boiler warm, we may infer that to keep the boiler warm and merely turn the machinery in readiness to meet a demand will take about 14lbs. of coal per day for every unit per hour the plant is capable of producing. In 1889, for the Society of Arts, tests were made of a Paxman compound engine, from which it appears that a boiler which when fully loaded consumed 40lbs. of coal per hour, required 4lbs. per hour to keep steam up to normal pressure when the engine was standing; that is, 10 per cent. of the coal used was used to maintain the steam pressure. Remembering that in addition we keep some of our machinery moving, this may be said to confirm the figures adopted. Thus, if the plant runs light all the year round 12,775,000lbs., or, let us say, 6,000 tons of coal will be consumed. If the plant runs fully loaded, 65,700,000lbs., or, let us say, 30,000 tons would be consumed. If we suppose the coal to be best smokeless it might cost 20s. per ton. Next we have water, oil, and petty stores; say, £600 and £3,000 in the two cases. Wages will be a little less if we run light than if we run fully loaded, and, of course, will largely depend on local circumstances; let us say, £5,000 and £7,500 in the two cases. This gives us substantially all the expenses which have to be met and our account will then stand thus :—

	Running Light.	Fully Loaded.
Fixed charges	£16,410	£18,750
Coal	6,000	30,000
Stores	600	3,000
Wages	5,000	7,500
	£28,010	£59,250

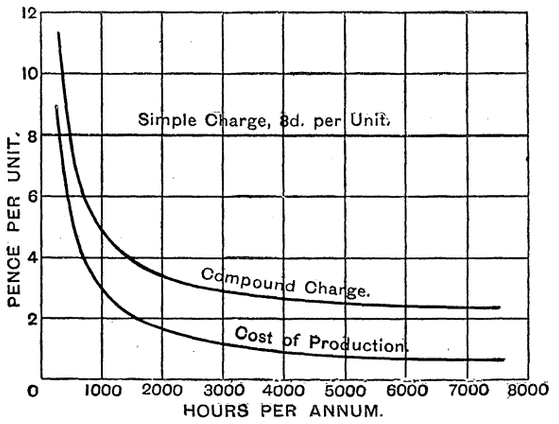
Thus the cost of merely being ready to supply 2,500 units per hour at any moment throughout the year will be £28,010, and the cost of actually supplying 2,500 units per hour for every minute in the year will be £59,250. The undertaker, therefore, who incurs the liability to supply, ought to receive £11 per aunum per unit per hour from those on whose behalf he incurs the liability, and if he receives the £11 he need not charge more than $\frac{1}{3}$d. per unit for what he actually supplies to cover his expenses. That these figures are fair approximations can be seen as follows :—According to this calculation the cost of supplying 2,500 units for one hour per day is £28,010 + 2,500 × 365 × $\frac{1}{3}$d. = £29,277, and the charge for the service at 8d. a unit would be £30,417; it is doubtful if such a supply would pay. On the other hand, an indicated horse-power on such a scale could certainly be supplied continuously for from £12 to £14 per annum, and according to this calculation an electrical horse-power will cost just under £18 per annum. No account is taken of expenses peculiar to companies, such as directors' fees and the cost of forming the company. It will also be noted that it is assumed that accumulators are not used.

The charge for a service rendered should bear some relation to the cost of rendering it. If it is a matter of open competition the matter will settle itself, for no one will for long be able to supply some customers at a loss, and recoup himself by exorbitant profits from others. If the matter be a case more or less of monopoly, the adjustment is less certain; thus, the Post Office charges $\frac{1}{2}$d. postage for a printed circular and 1d. for a written letter, the two costing the Post Office exactly the same. What a boon to the public it would be if the Post Office would charge more for printed trade circulars, which in nine cases out of ten are a nuisance to those who receive them. The supply of electricity is not quite a monopoly; companies compete with each other, and there is always the competition with other methods of illumination such as gas and paraffin. It is clearly to the advantage of the undertaker to secure all those customers whom it pays best to supply, and as far as may be, to compel those who are unrenumerative to adopt these other methods. The ideal method of charge, then, is a fixed charge per quarter proportioned to the greatest rate of supply the consumer will ever take, and a charge by meter for the actual consumption. Such a method I urged in 1883, and obtained the introduction into certain Provisional Orders of a clause sanctioning "a charge which is calculated partly by the quantity of energy contained in the supply and partly by a yearly or other rental depending upon the maximum strength of the current required to be supplied." In fixing the rates of fixed charges it must not be forgotten that it is improbable that all consumers will demand the maximum supply at the same moment, and consequently the fixed charge named might be reduced or some profit be obtained from it. There is no object in reducing the cost of electricity for lighting in the case of any customer much below the cost of equivalent lighting by gas, unless there are competitors in the field willing to do it, hence the current charge proportioned to the power supplied may safely be increased. In certain recent cases in which I am acting as engineer, the Board of Trade have sanctioned on my application, "for each unit per hour in the maximum power demanded, a charge not exceeding £3 per quarter, and in addition for each unit supplied, a charge not exceeding two pence." It is sometimes said as an objection to this method of charge, the public will object to pay a fixed charge whether they make use of their lights or not, and that, in fact, they will not pay it. The best answer that can be made is to give everyone the choice of being charged the maximum simple rate provided by the Order, or by the compound rate as they prefer. What is wanted is not so much an increased charge for those consumers whose lights are used for a short time, as such a special reduced charge for those whose lights are used long as will induce them to use the supply.

It is instructive to compare the cost to different classes of consumers of electricity and gas for lighting with 16-candle gas. Flat flame burners must be large and of first-rate quality to give more than two candles per cubic foot of gas per hour; the large majority of burners give much less than this even at their best, and as a rule the pressure of the gas is not regulated, and much gas is wasted as far as the production of light is concerned. Incandescent lamps give about one quarter of a candle per watt; hence a Board of Trade unit is equivalent to 125 cubic feet of gas. Thus we readily arrive at the following comparative table, the charge being at the rates recently sanctioned by the Board of Trade :—

Hours of use per annum.	Load Factor.	Price of Gas at which cost of lighting by electricity and 16-candle gas are equal.
480	5·5	5s. 4d.
960	10·9	3s. 4d.
1,440	16·4	2s. 8d.
1,920	21·9	2s. 4d.
2,880	32·9	2s. 0d.
3,840	43·8	1s. 10d.
7,680	87·6	1s. 7d.

In the accompanying curves are shown the cost of production, and the charge per unit at the compound and simple rate. The ordinates represent pence and the abscissæ the number of hours per annum the supply is used.



It is obvious that those whose user is long will find the electric light economical to themselves and that it will be profitable to the undertaker. With a cheap light which is free from the products of combustion there will be extensions for the hours of use. Shops may find it worth while to continue the light after closing, as an advertisement.

We have so far assumed that the supply of electricity is carried on without the aid of accumulators. Let us first compare the cost of an electric accumulator with the cost of a gas-holder containing the same possibility of producing light. A gas-holder is at present being put up in Manchester to hold seven million cubic feet of gas and is to cost complete with its tank £60,000. With 16-candle gas seven million cubic feet are equivalent to 56,000 Board of Trade units. Accumulators, capable of storing a ten hours' supply, cost about £50 per unit. The equivalent accumulator will therefore cost about £280,000. But this is not all; the gas-holder is comparatively permanent; the accumulators require frequent renewals and repairs; the gas-holder gives back all the energy put into it; the accumulators waste at least 20 per cent.; the gas-holder may be emptied as fast as you please; the accumulators, not faster than a certain rate without diminishing their capacity. Taking all into

Hosted by Google

consideration, the cost of storing energy by the aid of accumulators, and storing it in a gas-holder are quantities of a different order of magnitude. If no gas-holders were used, and all the gas had to be made just as it was wanted, its cost for lighting would be several fold what it now is, even if gas producers could be found capable of instantly varying the supply as the demand varies. The gas-producing plant would have to be enormously increased; so would the size of the mains, and so would the wages of labour. If electric power could be stored as cheaply as gas, there would soon be little hope that the gas companies would maintain their dividends.

Let us see from a financial point of view whether accumulators can be used economically for storing up electrical power continuously produced during the 24 hours, and used rapidly for a short time.

Assume that the whole of the plant with the accumulators is capable of supplying 40,000 lights for ten hours continuously, and that during that time half the power is supplied from the accumulators. Ten hours in the twenty-four hours is not an unreasonable allowance, for we have melancholy experience in London of continuous fog for days, and this would tax the plant we are considering to the utmost. We are to be ready, then, at any time on short notice to supply 40,000 lights, and to continue to supply them for ten hours. Compare the cost firstly of maintaining this state of readiness with the accumulators and with a plant without accumulators. We shall require a battery capable of giving 1,250 units for ten hours; such a battery costs not less than £50 per unit, or in all £62,500. To maintain it will cost from 10 to 15 per cent. on the cost; there will also be interest on the outlay and amortization, say in all 20 per cent., or £12,500 a year. If we assume that the batteries are distributed at the various points of the system of conductors, we may also assume that the charges for land and buildings will be much the same as for the plant without accumulators. The boilers, engines, and dynamos will be just one-half. The switch board and instruments will be much the same. But the conductors will be reduced, smaller or shorter feeders being necessary, probably £40,000 will go as far with accumulators as £50,000 without. The coal bill may be dispensed with entirely, as we may assume that steam could always be got up during the time in which the demand increased from nothing to one half of the maximum, and that therefore all the coal burned can be assumed to be burned for producing current. That is to say, we assume the quantity of coal burned is proportional to the quantity of electric energy, and that, therefore, when no electricity is actually used, no coal will be burned. The wages may be reduced, for we have only to be ready to run half the plant, and a small wage will suffice for attendance on the accumulators. The wages of linesmen and the like will remain the same. Assume the total wages to be £3,500 instead of £5,000, the account will then stand thus:—

Land	£1,000
Buildings	1,500
Rates	500
Accumulators	12,500
Boilers	1,050
Engines	1,080
Dynamos	675
Switchboard	300
Conductors	6,000
Wages	3,500
	£28,105

practically the same result as we obtained before.

Now consider another hypothetical case, which, of course, can never occur in practice. We are to supply 40,000 lamps for ten hours every day with the plant just described, charging the accumulators during twelve and a-half of the fourteen hours during which the light is not required, twelve and a half hours' charging giving ten hours' discharge of the same energy. The coal would cost the half of £30,000 if the machinery had to run the whole of the 24 hours. It has to run 22½ hours, but the boilers have to be kept warm the whole time, hence the coal will cost the half of £6,000 for keeping the boilers warm, and $\frac{22\frac{1}{2}}{24}$ths of the half of £24,000 for generating steam. The wages may fairly be taken as £4,750, and the account will stand:—

Land	£1,000
Buildings	1,500
Rates	500
Accumulators	12,500
Boilers	1,050
Engines	1,800
Dynamos	1,125
Switchboard	300
Conductors	6,000
Wages	4,750
Coal	14,250
Stores	1,425
	£46,200

The cost of supply for the same ten hours without accumulators would be as follows:—

Land	£1,000
Buildings	1,500
Rates	500
Boilers	2,100
Switchboard and conductors	7,800
Engines	2,760
Dynamos	1,725
Coal	16,000
Stores	1,600
Wages	6,000
	£40,985

a cost of about 11 per cent. less than where accumulators are used.

Putting it another way, the cost of being ready to supply and to continue to supply, is about the same whether accumulators are used or not; the additional cost of actually supplying current is about 40 per cent. more where accumulators are used than where they are not used. It may be safely inferred that the use of accumulators does not seriously alter the conclusions I have drawn as to the proper method of charging consumers for a supply of electricity.

The question of whether the great cost of a supply for short hours can be removed by the use of accumulators may be looked at in another way. Will it pay a consumer to put in his own accumulators and charge them from the station supply? We may reasonably suppose the undertaker will remit the fixed charge in consideration of the consumer only taking his current at slack times. His accumulators, if they are to be of capacity to maintain his supply through a foggy day, will cost him £50 per unit per hour (or per kilowatt), and the annual charge in respect of them will be £10 per year, which, if we add a rent for the space the battery occupies, gives us a charge not differing materially from the fixed charge made or suitable to be made by the undertaker. But in order to obtain 2d. worth of electricity he must purchase 2½d. worth for charging his battery.

A word or two more about the use of accumulators. These have certainly improved, and they will continue to improve. They will become more durable and more economical of power in working, and their first cost will become less. An inspection of my tables of cost shows that a very little improvement would render them valuable even in very large stations for the mere purpose of diminishing the machinery required, by storing the energy developed at slack times to be used in busy times. The certainty of improvements in accumulators, and the possibility that the improvement may be considerable, is a strong argument for the use of the direct current wherever it is not precluded by the distance of transmission being too great.

It will be noted that I have assumed a very large station. Accumulators have another use which greatly increases their advantage in smaller stations. There are many hours in the twenty-four when it is absolutely certain that the demand will be small. If accumulators are used the attendance of the staff may be dispensed with during those hours, and a considerable sum in wages will be saved. The proportion of wages to the whole of the charges is much greater in small stations than in large. In most small stations giving continuous supply, accumulators ought to be used notwithstanding their expenses and defects, and I believe the day is not far distant when they ought to be used in connection with most large stations also.

If, instead of a continuous current, an alternating current with transformers is used, the modification in the account will be that the cost of conductors will be diminished, but the cost of transformers will have to be added. If the distances are small, the increased cost of transformers will exceed the saving in the conductors; if the distances are considerable, the cost of transformers will be less than the saving of conductors. In both cases the general character of the result will be the same as before, the cost of being prepared to give a supply will be considerable, and the cost of actually giving the supply will be much smaller than is generally supposed. Indeed, with the alternating current this peculiarity will be even more marked, for the machinery has not only to be kept in motion, however small the consumption may be, but a certain current must be maintained in every transformer. With the best transformers this current may only have an energy 1½ per cent. of the energy of the current when the transformer is fully loaded. This would increase the coal bill in the case considered by about £500 per year whether the supply was used or not.

It is possible, indeed probable, that some of my assumed figures may be shown to be too high or too low for the generality of cases. It is of no moment; let each one take any figures he pleases within reason; let him assume that the supply of electricity is made by any system he pleases; he will arrive at a result broadly similar to mine. To be ready to supply a customer with electricity at any moment he wants it will cost those giving the supply not much less than £11 per annum for every kilowatt, that is for every

Hosted by Google

unit per hour, which the customer can take if he wishes; and afterwards to actually give the supply, will not cost very much more than ½d. per unit. This is the point I have been labouring to impress, for I take it it is essential to the commercial success of electric supply. It is hopeless for electricity to compete with gas in this country all along the line if price is the only consideration. But with selected customers electricity is cheaper than gas. Surely it is the interest of those who supply electricity to secure such customers by charging them a rate having some sort of relation to the cost of supplying them.

FURTHER EXPERIMENTS ON THE SPECIFIC INDUCTIVE CAPACITY OF ELECTROLYTES.*

BY EDWARD B. ROSA, PH.D.

I. In a note appended to an article on the "Specific Inductive Capacity of Electrolytes," in the *Philosophical Magazine*† for March, 1891, I referred briefly to some experiments then under way on the behaviour of glass in a non-uniform electrical field in different liquids. The experiments were undertaken with a view of verifying the results of previous work, which indicated that water and alcohol possess genuine specific inductive capacities much larger than most other liquids, although not infinite as sometimes stated.

The energy of an electrical system is

$$W=\frac{1}{8\pi}\iiint K H^2 \, dv.$$

Supposing the media isotropic, and the system to consist of a solid dielectric immersed in a fluid, we may write

$$W=\frac{K}{8\pi}\iiint H^2 \, dv+\frac{K_1}{8\pi}\iiint H_1^2 \, dv,$$

where the first integral is to be taken throughout the fluid and the second throughout the solid. If $K_1 > K$ the force in the fluid near the solid is increased, while within the solid it is decreased, as compared with the forces in the absence of the solid. The total energy is, however, increased by the presence of the solid, and if the field is variable the solid is acted upon by a resultant force which urges it toward the stronger parts of the field. If, however, $K_1 < K$ the solid tends to move toward those regions where the electric force is less. This is analogous to the case of magnetic and diamagnetic bodies in a magnetic field.

These considerations lead one to expect that glass (for example) would go toward the stronger parts of the field in air, turpentine, and other dielectrics having a small value of K, and toward the weaker regions of the field in water and alcohol. Moreover, since K for water and alcohol is very large, the glass would experience a force many times greater in water in the one direction than in air in the other. These anticipations have been completely realised.

The Apparatus.

II. In the experiment there were employed two pairs of electrodes, M_1, N_1 and M_2, N_2, shown in section in Fig. 1. They were of platinum, 0·9 cm. in diameter, 5·0 cms. long, and their centres were 2·6 cms. apart. M_1 and M_2 were joined to one pole of a battery furnishing any desired potential up to 140 volts; N_1 and N_2 were joined to the other pole; and a rotating commutator served to give alternations of 50 to 100 per second. Two cylinders, S_1, S_2 of glass, mounted on glass stems, were carried on the arms of a torsion balance, d being the axis of rotation. The deflection was measured by a telescope and scale, and the force determined in absolute measure. The cylinders of glass were subsequently replaced by cylinders of paraffin, beeswax, and other dielectrics, and carbon and brass among conductors. The force f on the cylinders is perpendicular to the direction of the lines of electric force and is proportional to $\frac{d(H^2)}{dy}$ where H is the electric force.

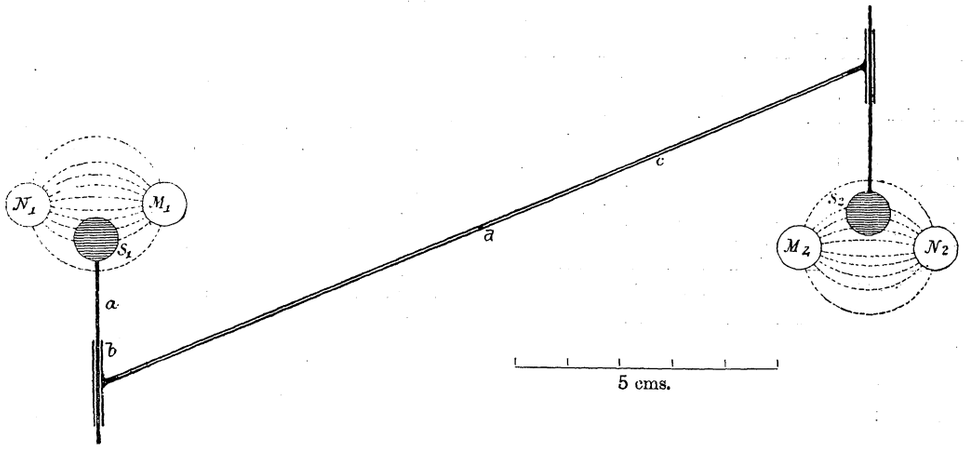
$$H=C\frac{2A}{A^2+y^2},$$

where C depends on the difference of potential between the electrodes. f has a maximum value at a point P where

$$y=\frac{A}{\sqrt{5}};$$

that is, about a quarter of the distance between the axes of the cylinders from the origin. About this maximum point the force varies but little for a considerable distance. This is then a particularly favourable place to put the solid S, as an exact knowledge of its position is not necessary. A fairly accurate adjustment was, however, always made, by first bringing the solid just between the electrodes where the resultant force is zero, and then turning the torsion head, by means of a lever reaching to the telescope, always through the same angle. The resultant force f on the solid is inversely proportional to A^3, and directly proportional to the volume of the cylinder, that is to the cube of its linear dimensions. *Thus changing the linear dimensions of the system does not alter the force on the solid.* The following is a brief statement of the results observed:—

1. Glass cylinders in air, petroleum oils, bisulphide of carbon, turpentine, and benzene are attracted; that is, move into the stronger parts of the field.



2. The force is least in air and greatest in turpentine; in short, is greater in those media having a greater specific inductive capacity, all, however, being considerably less than that of glass. This indicates that the principal change of energy is in the fluid medium.

3. In water, alcohol, and ether (the latter containing water and alcohol as impurities) glass is repelled, the forces of repulsion being nearly in the ratios of 9 : 3 : 1 respectively. In bisulphide of carbon containing about 20 per cent. of the same ether, glass is attracted, but with about 40 per cent. it is repelled.

4. The force of repulsion on glass in water is over 60 times as great as the attraction in air. Since this is approximately the value of the specific inductive capacity of water it suggests, as in the case of glass in liquids of low specific inductive capacities, that the chief change in energy due to the presence of the glass is in the fluid media.

5. The force on the glass is proportional to the square of the difference of potential between the electrodes, and, therefore, to H^2. In the case of water and alcohol this was verified quite accurately; and in the case of the other liquids, where the forces were much smaller, it was verified approximately.

Conducting Cylinders.

III. If the cylinder is a conductor and is surrounded by a non-conducting medium, the lines of force are drawn toward it, as lines of magnetic force are gathered up by a piece of iron put into a magnetic field. The resultant force is *always one of attraction toward the electrodes.* This follows from the tendency of the lines of force to shorten, and being more numerous on the side toward

* Abstract from the *Philosophical Magazine.*

† The results obtained at that time by Mr. Rosa, together with others obtained by Herr Tereschin and Herr Lecher, were republished in *The Electrician*, April 3, 1891, page 661.

Hosted by Google

the origin, the conductor is drawn in that direction. If the surrounding medium is a conductor, the case is not modified providing the solid is a very much better conductor. Thus, suppose the cylinder is carbon and the medium water. The latter is a fair conductor, yet carbon conducts millions of times better than does distilled water, and the lines of force will be arranged sensibly the same as though water were a non-conductor and carbon a perfect conductor. The resultant force on a cylinder in a given field will evidently be proportioned to the specific inductive capacity of the medium of the field. This is a much simpler case than that of a dielectric solid in a liquid, where the conductivity of the liquid and the specific inductive capacity of the solid affect the result. As before, an accurate adjustment of the position of the conducting cylinders is not necessary, and using the same cylinders with the same difference (or known differences) of potential, this would seem to be an excellent method of measuring the specific inductive capacity of liquids. Accordingly, cylinders of carbon (cut out of an arc-light carbon) were mounted in the torsion-balance and the force of attraction under various conditions measured.

1. The force, as we should expect, is accurately proportional to the square of the difference of potential for air and all liquids, conducting and non-conducting.

2. The force is approximately proportional to the volume of the cylinder. This was found to be roughly true for three pairs of cylinders of nearly equal length but of very different volumes, *i.e.*, 0·73, 5·7, and 10·0 cubic cms. respectively. The force increased somewhat faster than the volumes, which would be expected, as the larger cylinders extend farther into the stronger parts of the field near the electrodes. For small changes in the volume the force may be taken as proportional to the volume.

3. The following tables give series of measurements made with the second pair of cylinders (volume 5·7 cubic cms.) in air and turpentine. Other measurements agreed with these almost exactly.

Table I.—*Air.*

	Mean for 100 volts		4·34 ,,

$$\frac{4\cdot34}{1\cdot815} = \mathbf{2\cdot39} = \textit{specific inductive capacity of Turpentine.}$$

In the same way other liquids were treated, and the following values of their specific inductive capacities obtained :—

Water at 16°·5 C.	K=70.
Alcohol, about 93 per cent.	K=30·9.
Ether (with water and alcohol impurities)...	K= 8·4.
Turpentine	K= 2·39.
Petroleum oil, 300deg. test	K= 2·04.
Petroleum oil, light illuminating.....	K= 1·97.

The difference between the above value for alcohol and that previously given for absolute alcohol (25·7) is readily accounted for by the water present in this. Pure ether has a much smaller value than that given above.

This method is capable of giving tolerably accurate results, although it cannot be used with heavy oils ; for the force to be measured is small and the volume of the cylinders is considerable ; hence the latter move very slowly through a quite viscous liquid. The method given in the paper already referred to is applicable to such liquids, and is perhaps more convenient for all.

THE PARSONS STEAM TURBINE.*

In December last a condensing steam turbine, combined with a 100-kilowatt alternate-current dynamo, was tested, when it was found that the consumption of steam was 37lb. per electrical unit when the machine was running under full load, 39lb. per unit when the load was 50 units per hour, or one-half of the full value, and 43lb. per unit when the load was reduced to one-third of its full value.

A further series of trials have been made during last month, with the object of testing how far the efficiency has been improved by certain recent changes, and by the use of superheated steam. The same turbine was used in these as in the former trials ; but some additional rings of turbine blades were inserted at the high-pressure end to enable it to deal more effectively with pressures up to 115lb. per square inch (absolute). The chief factor in the improvement which has now been brought about is the use of moderately superheated steam, resulting in a reduction of about 27 per cent. in the steam consumption. There is nothing in the construction or working of the turbine to make it likely that the use of superheated steam will be attended by any drawbacks such as have been experienced in engines of the ordinary type. The steam works without lubrication, it comes into contact with no rubbing surfaces, and there is no packing to be injured.

A general view of the plant tested is given in elevation in Fig. 1, and in plan in Fig. 2. The turbine case (*a a*) contains a series of seven revolving discs, from the surface of which the turbine blades project. They are arranged, on each disc, in a series of concentric rings. The fixed guide-blades stand in spaces between these rings, being carried by annular discs, which are fixed to the case. Thus each revolving disc, with its neighbouring fixed disc forms a series of outward-flow turbines, the steam entering the series inside the smallest ring of blades and escaping at the circumference into a channel, which conducts it between the back of the revolving disc and of the next fixed disc to the inside of the next series of rings. The arrangement will be understood by reference to Fig. 3, which is a section showing the first three turbine discs. The heights and apertures of the turbine blades on each disc are adapted to the increasing volume of the steam as it expands from an absolute pressure of 115lb. per square inch to an absolute pressure of 1lb. per square inch. The first six discs, which are each 15in. in diameter, are designed to expand the steam to about atmospheric pressure, the remainder of the expansion being performed in passing the seventh disc, which is $26\frac{3}{4}$in. in diameter, and has (unlike the other six) a double series of rings of blades, one series on each side, through which the steam flows "in parallel." The height to which the turbine blades project above the discs in which they are secured varies from $\frac{3}{16}$in. to 1in. The whole number of rings of moving blades in the machine tested was 35. The blades are made of strong sheet brass, and show no sign of wear after continued use. Steam enters the turbine case at one end, through a double-beat valve shown in Fig. 3, and after passing the successive turbine discs, is discharged at *b* (Fig. 1) to a condenser. The longitudinal pressure on the turbine shaft, due to the one-sided character of the six smaller turbine discs, is balanced at the high-pressure end by a revolving baffle piston (Fig. 3), with a number of deep grooves on its circumference, which are entered by corresponding projections on a fixed bush resembling a thrust-block. Any small amount of longitudinal thrust which may remain unbalanced is received by an adjustable grooved thrust-bearing at the end of the spindle, beyond the main bearing. This, which is contained in the oil-box *c* (Fig. 3), is shown to a larger scale in section in Fig. 4. The thrust-bearing *d* (Fig. 4) consists of seven collars on the spindle revolving in a grooved bush, which is split longitudinally into halves with separate longitudinal adjustment to allow any wear to be taken up, so that end-shake is prevented, and the endwise position of the shaft is maintained with great precision. This device also gives a means of regulating the amount of clearance over the tips of the turbine blades. The thrust-bearing, like the main bearing, runs in a bath of oil. The main bearings are of a special construction which is admirably adapted to ensure easy running at a high speed, and to damp out vibration. The shaft (Fig. 4) rotates in a phosphor-bronze sleeve, outside of which are slipped three concentric steel tubes fitting loosely over one another. The outermost tube is a loose fit in the casting which forms the seat of the bearing. Oil is continuously and freely fed to the bearing from a cistern above, under a head of some 6in., and drains into a chamber below, from which it is automatically pumped back to the cistern. In this way the small clearance between each tube or sleeve and the one outside of it is kept charged with a film of oil, with the effect that while the shaft retains a necessary small amount of freedom to adjust itself by lateral displacement, the viscosity of the films acts as a powerful damper to prevent oscillation from being set up. The working of the bear-

ing is perfectly satisfactory, and the damping action is so great that the shaft may even be put considerably out of balance without causing the vibration to become excessive or making the bearings run hot. In the ordinary conditions of balance the shaft carrying the turbines, the main armature, and the exciter armature, runs at 80 revolutions per second with a steadiness and quietness which are most remarkable.

The shaft passes out of the turbine case at each end through a lantern-brass or steam-gland. The whole shaft is in three lengths : the first part carries the turbines, the second carries the armature of the main dynamo *g* (Fig. 1), and the third part that of the exciter dynamo *h*. The parts are coupled by means of a square-bored sleeve slipped over squared ends. The couplings are placed in the middle of long double bearings at *j* and *k*. These, as well as the end bearing at *l*, are all formed by concentric tubes, and work drowned in a sea of oil, as already described for the other end bearing. The oil chambers are connected by pipes, so that a single oil-pump maintains the circulation in all. The pump, which is shown at *m* in Fig. 1, is driven by an eccentric which receives its motion from a worm (*n*) on the main shaft, working in oil, between the main bearing and thrust bearing of Fig. 4.

The governing of the machine tested was accomplished by admitting the steam to the turbine in a series of gusts by the periodic opening and closing of the double-beat lift-valve shown in Fig. 3. The duration of each gust was controlled by an electric solenoid, which was connected as a shunt to the field magnets, but was compounded so as to keep the volts constant. The core of the solenoid was hung from the end of a long lever (Fig. 1). The fulcrum of this lever was periodically moved up and down by means of a link connecting it with the eccentric, which also served to drive the oil-pump. The short end of the lever controlled the valve of the steam relay. Each periodic movement caused a gust of steam to be admitted to the turbine, the duration of the gust depending on the height of the distant end of the lever. The effect was, that at full load the gusts became blended into an almost continuous blast, the lift-valve closing only momentarily, or not at all, in each of the periodic movements, which caused no material throbbing of speed nor any variation of volts sensible on a voltmeter. The whole load, amounting to over 130 E.H.P., was thrown on and off suddenly, without causing more than a momentary variation in the volts.

By applying an indicator at the admission end of the turbine chamber, below the double-beat valve, observation was made of the pressure during the periodic admission of steam; this was done by pulling the paper-drum of the indicator as steadily round as possible by hand while the pencil rose and fell. Figs. 5 and 6 are examples of diagrams obtained in this way. In Fig. 5 the load was about one-half the maximum ; in Fig. 6 it was about three-quarters.

Most of the trials have been made with a continuous-current armature, wound to give 400 amperes at 250 volts. The results of the continuous-current trials, where the electrical measurement of the work done is of a perfectly simple and straightforward character, are in close agreement with those of the alternate-current trials. The main armature was about 2ft. 6in. long over the body by 9in. in diameter. The weight of copper on it was only 33lb., or $\frac{1}{3}$lb. per kilowatt of output.

Steam for the turbine was supplied at a pressure of 100lb. per square inch by gauge. In all the statements which follow of the results of these trials, the quantity of feed-water named is the gross quantity supplied to the boiler, no deduction having been made for leakage, blow off at the safety valve, or other loss.

Three separate set of trials were made, August 11 to 15, 1892. In the first set the steam was superheated by means of the hot gases from the boiler furnace only. The temperature approached but did not exceed 400°F., which, as the boiler pressure was 100lbs. per square inch above the atmosphere, corresponds to about 60° of superheating. In this set of trials the continuous-current armature was used, and the amount of feed-water was determined for six different grades of output, from no electrical load up to a load in which the output was at the uniform rate of 102 Board of Trade electrical units per hour, the current being spent on a bank of coils. The results of this set of trials are set forth in tables and curves. The output stated is the amount of electrical work done upon the external circuit, and does not include the output of the exciter. The volts were measured by three Cardew voltmeters, which were tested against each other, and one of them against a Thomson balance. The amperes were measured in the following way : — A low-resistance frame consisting of many bare thick wires of platinoid grouped in parallel, was arranged as a shunt to a mirror galvanometer, which was provided with a strong controlling magnet, so that the whole current of about 400 ampéres could pass without causing an inconveniently great deflection, and without heating the wires of the shunt materially. In series with this was placed (1) an Evershed ampèremeter which had been carefully calibrated by reference to a Thomson balance, and (2) two Siemens' electro-dynamometers, one of which could take the strongest current while the other was suitable for comparatively weak currents only. The constant of the shunted mirror galvanometer was determined in the low-power trials by comparing its deflection with the readings of the Evershed and of the more sensitive of the two Siemens' instruments. These were then cut out to allow stronger currents to pass, and in the trials under heavy load a further check on the constant of the mirror galvanometer was furnished by the readings of the larger electro-dynamometer. The mirror galvanometer, the constant of which remained unaltered throughout, served to connect the readings of all the currents, from the lightest to the heaviest loads. The agreement between the various measurements was perfectly satisfactory. In the second set of trials the object was to test the effect of additional superheating. In the third set of trials the alternate-current armature was used, giving 2,000 volts at a speed of 4,800 revolutions per minute, which made the frequency of alternations 80 periods per second. Here the current was directly measured by the Evershed and Siemens' instruments, and the volts were determined by (1) a Cardew voltmeter furnished with a resistance specially wound to enable it to read 2,000 volts, and independently (2) by another Cardew voltmeter with a step-down transformer having a ratio of one to twenty. The output was taken to be the product of the effective volts and the effective amperes. In these alternate-current trials the electrical energy was absorbed by a water resistance formed by sticking two rods, to serve as terminals, some ten yards apart in a pond, the amount of resistance between them being adjusted by pulling the rods out or in to expose more or less of their surface to contact with the water. In this third set of trials the steam was moderately superheated, as in the first set, by the hot gases of the boiler flue only—its temperature again approaching 400° Fahr. The close agreement of the results with the corresponding continuous current trials is important, as supplying evidence that in alternate-current trials conducted in this manner the effects of lag in the external circuit are immaterial ; in other words, that the electrical work is properly measured by multiplying the effective volts by the effective amperes. The difference between the alternating and continuous-current measurements is less than 1 per cent. of the output at full load.

The results are exhibited in tables given in the Report, and by the curves, Figs. 7 and 8. The rate of electrical output is shown in relation to the whole consumption per hour, in Fig. 7, and in relation to the consumption of feed-water per electrical unit in Fig. 8. The upper line in each diagram refers to the first set of the present trials—which were made with continuous currents and moderate super-heating. The points of observation are marked by a dot within a circle. The points marked by a cross within a circle, which lie very close to this curve and a trifle below it, are for the tests made with alternating currents. The lower line in each diagram relates to the trials with extra superheating. The points of observation are marked by a line across a circle. To facilitate comparison, the amount of feed-water used per electrical unit at various rates of output, as measured from the curves of Fig. 8, is given numerically in the following table :—

Consumption of Feed-Water at Various Rates of Output, with Superheating.

Rate of output in electrical units per hour.	Feed-water per electrical unit.	
	With superheating to about 400°F.	With extra superheating to 465°F.
20	48	—
40	34½	32
60	30½	28½
80	29	27½
100	28½	(27)

The trials show that a very considerable advantage is realised by moderate superheating, which requires less than 3 per cent. of the heat taken up in the boiler. With steam superheated to this extent the consumption of full load is less by one-fourth than the consumption in the old trials. It is clear, however, that superheating is responsible for a great part of the difference. Apart from the increased volume of the working substance the advantage of superheating is to be ascribed in part to the prevention or reduction of the condensation at entry, which would otherwise take place in consequence of the intermittent character of the admission, and in part to its influence in keeping the steam dry during its expansion, and thereby reducing the internal resistances. At full load, when the steam enters in a nearly continuous blast, the latter effect is no doubt the more important.

After discussing the advantage of superheating, the report goes on to state that the general result of the trials is to demonstrate that the condensing steam turbine is an exceptionally economical heat engine. The application to it of moderately superheated

Hosted by Google

steam has put the performance of the turbine on a level with that of the best steam-engines of the ordinary type. A consumption of 27lb. or 28lb. of steam per electrical unit, at full load, and 30lb. or 32lb. at half load, is a result that does not need to have its significance emphasised. The efficiency, under comparatively small fractions of the full load, is probably greater than in any steam-engine, and is a feature of special interest in relation to the use of the turbine in electric lighting from central stations.

The consumption of 28lb. per unit corresponds to 20·9lb. per electrical horse-power-hour. To facilitate comparison with other engine trials, it may be useful to estimate from these results what may, by analogy, be called the "indicated ' horse-power of the turbine—that is to say, the mechanical work done by the steam on the turbine blades. The curves of Fig. 7 are nearly straight lines, and by prolonging them backwards to meet the base-line produced, it appears that the *idle work*—that is to say, the work done without useful output, was equivalent to 27 kilowatts, or 36 H.P.

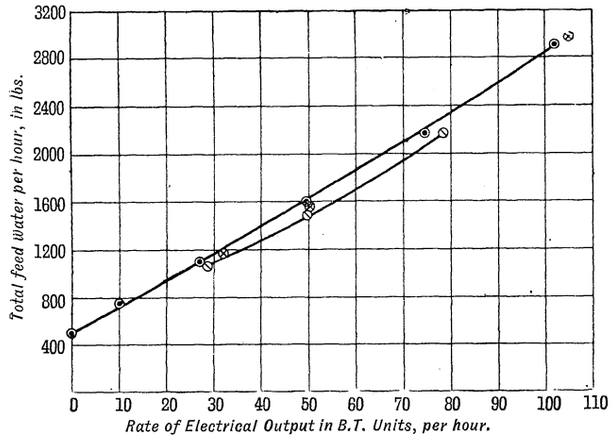

FIG. 7.—Trials of Parsons' Steam Turbine and Dynamo, August, 1892. Top Curve—Steam superheated to about 400°F. ; Dot and Circle = Continuous Current Trials ; Cross and Circle = Alternating Current Trials. Lower Curve—Steam superheated to 465°F. ; Continuous Current Trials.

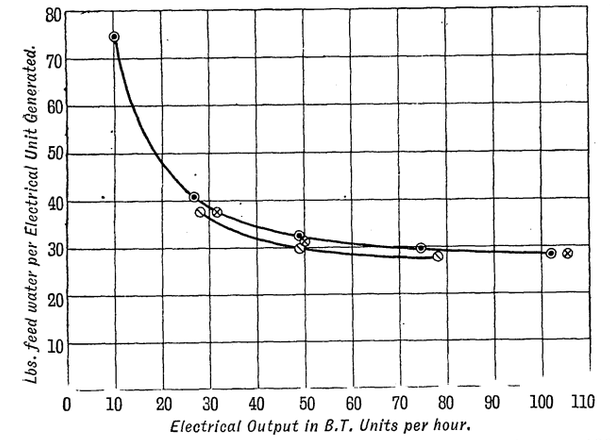

FIG. 8.—Trials of Parsons' Steam Turbine and Dynamo, August, 1892. Top Curve—Steam superheated to about 400°F. ; Dot and Circle = Continuous Current Trials ; Cross and Circle = Alternating Current Trials. Lower Curve—Steam superheated to 465°F. ; Continuous Current Trials.

The effective work at full load, the equivalent of 100 electrical units per hour, was 134 E.H.P., and it will be nearer the truth to assume that the effective work was not more than 75 per cent. of the total work. This would make the total work about 179 H.P. On this basis a consumption of steam at the rate of 28lb. per electrical unit is equivalent to 15·7lb. of feed-water per "indicated" horse-power-hour, and 27lb. per unit is equivalent to 15·1lb. per "indicated" horse-power-hour. Similarly, the consumption of half load is equivalent to about 17lb. per indicated horse-power-hour.

The City Lighting.—Notice is given that a faculty has been granted to authorise the construction of a transformer chamber for the City of London Electric Lighting Company in the churchyard of St. Benetfink, and, if found to be necessary, the removal of the remains of persons buried there.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, November 11th.

PHYSICAL SOCIETY.

5 p.m. Ordinary Meeting. Continued discussion of the Papers by Mr. Williams and Mr. Sutherland : "Dimensions of Physical Quantities" and "Molecular Forces."

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Two short Papers to be read on subjects connected with the testing and calibration of electrical instruments.

TUESDAY, November 15th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be read with a view to Discussion :—(1) "Halifax Graving Dock, Nova Scotia," by the Hon. R. C. Parsons, M.A. ; (2) "Cockatoo Island Graving Dock, New South Wales," by E. W. Young, M.Inst.C.E. ; (3) "The Alexandra Graving Dock, Belfast," by W. Redfern Kelly, M.Inst C.E. ; (4) "Construction of a Concrete Graving Dock at Newport, Monmouthshire." by Robert Pickwell, Assoc.M.Inst.C.E.

ROYAL VICTORIA HALL.

8 p.m. Lecture : "Electric Sparks and Lightning Flashes," by Dr. W. D. Halliburton, F.R.S.

WEDNESDAY, November 16th.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary Meeting. Papers to be read :—(1) "Thunderstorm, Cloudburst, and Flood at Langtoft, East Yorkshire, July 3, 1892," by John Lovel, F.R.Met.Sc. ; (2) "On the Measurement of the Maximum Wind Pressure, and Description of a New Instrument for Indicating and Recording the Maximum," by W. H. Dines, B.A. To be followed by a special business meeting.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Opening Address by Sir Richard Webster, Q.C., M.P., Chairman of the Council.

THURSDAY, November 17th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be read (in the event of the discussion on Mr. Swinburne's Paper being terminated) :—"Experimental Researches on the Alternate Current Transformer," by Dr. J. A. Fleming, F.R.S.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting. Paper to be read :—Note on "The Refractive Indices and Magnetic Rotation of Sulphuric Acid Solutions," by S. U. Pickering, F.R.S. ; also other Papers.

FRIDAY, November 18th.

INSTITUTION OF ELECTRICAL ENGINEERS.

7:30 p.m. Annual Dinner at the Criterion Restaurant.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

CYRUS W. FIELD.

With "THE ELECTRICIAN" for Oct. 28 was issued a Fine Steel-Plate Portrait of the late CYRUS W. FIELD, Pioneer of Ocean Telegraphy.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

Only a fortnight ago we turned to a list of the Council of the Institution of Electrical Engineers and made an analysis of its members, arriving at very much the same result as that which will be found in our Correspondence Columns. We alluded to this analysis in our leading article on October 28th, but the object in view was altogether different from, and the opinions which we then expressed were in some respects opposed to, the conclusions which are drawn by our Correspondents. We agree at once with them that the Council does not represent the profession of electrical engineering, but it cannot be said to have done so at any time, and has none the less done excellent work. In many respects, no doubt, the principles and procedure of the Institution of Civil Engineers may with advantage be imitated by other societies aiming at similar objects, but to copy it in constitution and in routine is, we hold, quite a mistake, if only because of the great difference between the objects of the two bodies. The older Institution embraces all branches of the profession, but strictly civil engineering rather than mechanical or constructive or purely scientific engineering is practised by the majority of those who have attained the standing of members. The younger Institution, on the other hand, consists of men whose work is of a much less professional character. A very large proportion are engaged in manufacture and practically in trade. Trade matters, however, are very rarely discussed at its meetings, and many of the most influential commercial men are never seen at the meetings. The contents of the Papers read are quite sufficient to prove that it is essentially a scientific body, and that the Papers and the discussions thereon are a good test, we need only point out the perfectly

Hosted by Google

voluntary character of these contributions. We believe that, as with all other such institutions, the Council is glad enough to receive Papers at the beginning of the session, and is generally overwhelmed at the end, and that refusal of Papers is somewhat exceptional. This Institution, like that of the Civil Engineers, is, therefore, largely what its members choose to make it. Anything that will improve the Institution as a whole should, of course, be adopted, but whether much can done in this direction by modifying the constitution of the Council should be carefully considered.

Electrical engineering differs widely from civil engineering in that it is, on the one hand, far more scientific, and, on the other, much more closely connected with trade, so that there is left but little of the professional element. This new industry depends in a most important degree upon theory, and some branches of it are well nigh swamped with science and mathematics. Civil engineering and mechanical engineering on the other hand develop year by year, and scientific methods and principles are gradually introduced, but not even the influence of technical colleges can smother sound, well-established engineering practice with scientific theories. In electrical engineering there is no such thing as sound, well-established practice. New discoveries such as the drehstrom, or the PARSONS' turbine, threaten to upset our ideas of construction, and we have to keep our minds prepared for the overthrow of theories and for the discussion of brand new hypotheses. If there were not enough of science in the electrical industry to make this the basis of the Institution, the introduction of another element might be advisable, but being composed mainly of science and trade, the Electrical Trades' Section of the London Chamber of Commerce forms an excellent complement to the Institution of Electrical Engineers. Another set of men meet at Botolph House, and experience has shown that the functions of the two bodies do not clash, and that they can work well together when common action is necessary.

If this view of the Institution of Electrical Engineers be a sound one—and we merely throw it out as a suggestion—the preponderance of professors on the Council is no evil. On the contrary, the Institution should be congratulated on attracting nearly all the professors who are actively engaged in electrical teaching or research in London, so long as there are enough men on the Council who are engaged in the practice of engineering to keep it from drifting into a mere electrical society. To tamely imitate the Institution of Civil Engineers is but to compete with it, and this is folly. For not only do many men belong to both Institutions, and some of these will occasionally offer their Papers to the older society, but the Civil Engineers often invite Papers from those who do not in any way belong to their body, as for example, during last session, Mr. ROBERTS-AUSTEN and Mr. J. SWINBURNE. While suggesting that the Institution of Electrical Engineers should specialise rather than compete, it is clear that its objects should not be narrowed, and above all, that it should be properly managed. The constitution of the Institution has not become so crystallised that movements of this kind must either fail, or be carried on with a rather unpleasant struggle. If there are indeed enough engineers with sufficient time to devote to the matter, it would be for the good of all that they should come forward. The only hint that our correspondents give as to the type of member they desire to see elected into the Council is that they should be actively employed in constructive work.

Fate having thus decreed that electrical engineering should be peculiarly scientific, it seems to us that it offers a particularly favourable opportunity for the continued existence of a Society which should be equally representative of Science and Engineering, of Theory and Practice. It is, we know, almost an axiom with some, that such a combination is a physical impossibility, and that, sooner or later, a divorce is certain to take place. However that may be, the attempt is surely worth making, and the first element of success is that the two extreme sections of such a Society should be thoroughly permeated with the spirit of compromise, and if any body of members can show that their numerical representation on the Council is insufficient, and that an appreciable good will result from a more arithmetically accurate state of things, there should be no reluctance in giving way. On the other hand, practical men might forego some of their disparagement of theorists. We await with interest the outcome of this movement.

OBITUARY.

EDWARD GRAVES.

It is our painful duty to record the death on Wednesday morning of Mr. Edward Graves, Engineer-in-Chief to the British Post Office Telegraphs. Mr. Graves had been a sufferer from diabetes for a considerable time past, but continued at his post until within a few days of his decease.

Mr. Graves was born in February, 1834, and after a brief connection with the North Eastern Railway Company, he first became connected with telegraphy in 1852, when he entered the service of the Electric and International Telegraph Company, at York, under Mr. de Chesnel, for whom he acted during a prolonged illness, and in 1856 succeeded, as Superintendent and District Engineer for the East Coast of England and Scotland, extending from London to Aberdeen. As the Company's system developed the district was divided, and at the transfer of the telegraphs to the State in 1870 Mr. Graves was made divisional engineer for the northern district, with headquarters at York. Possessed of great administrative ability and financial acumen, his services were employed in defending the interests of the Post Office during the arbitrations of 1874-8 between the Department and the various railway companies who were entitled to compensation under the Telegraphs Act of 1868, and the success of his efforts was mentioned by Sir Richard Baggallay, then Attorney-General, and other eminent counsel connected with the cases, and received official recognition by the Department. In 1878 Mr. R. S. Culley, the engineer-in-chief, retired from active service, and Mr. Graves was appointed to succeed him in that office, and immediately re-organised the engineering staff. He was a delegate to the Paris Electrical Conference in 1881, and received the Cross of an officer of the Legion of Honour from the French Government; he was a member of the Channel Tunnel Defence Committee in 1882; of the Electrical Standard Units Committee and of the Royal Commission on Electrical Communication with Lighthouses and Lightships, whose report is expected shortly. Mr. Graves was one of the early members of the now Institution of Electrical Engineers, of which he was for many years honorary treasurer, and in 1888 was its president.

The Junior Engineering Society.—At a meeting of this Society on Friday last at the Westminster Palace Hotel, Sir Edward Reed, in vacating the chair, spoke of the great value of such opportunities as those which are afforded by this Society for promoting intercourse between the elder members of the profession and those who had yet the battle of life to fight. Dr. J. Hopkinson, the new President, delivered a very interesting address which will be found in another column. In seconding a vote of thanks for this address, a member, whose name had better be withheld, alluded with most naïve contempt of court to Dr. Hopkinson as having contributed greatly to the advance of electrical engineering by the development of the dynamo and the invention of the three-wire system.

EARTHING THE MIDDLE CONDUCTOR OF A THREE-WIRE SYSTEM.*

BY VON PH. SEUBEL.

For some time past the *Elektrotechnische Zeitschrift* has been publishing communications on this subject, more particularly in regard to the position which American authorities are taking for and against this matter. The *Elektrotechnische Zeitschrift*, No. 28, contains a communication from the *Allgemeine Electricitäts Gesellshaft*, in which a lecture is mentioned which was given by me before the Association of the Edison Illuminating Companies in 1889. I now beg to report on further experience in this matter. Herr Gräwinkel up to the present has not given us any proof of his assertion made in No. 23, that this putting to earth of the third wire affects the telephones. His further assertion that in America it is not allowed for reasons of public safety can only refer to an order issued by the Board of Electric Control of New York. However, this purely political body can hardly be regarded as a competent authority on this question. It may be at once said that the Edison Illuminating Company of New York has replied to the demand of that body that they will only comply with their order to again insulate the third wire under the express conditions that the Board of Electric Control takes the responsibility for all the consequences arising from such action. As far as I am aware, up to the present, the Board of Electric Control have not agreed to take on themselves this responsibility, and the third wire remains now as it was before put to earth.

It was only after careful discussions between a number of the officers of the Edison General and the Edison Illumination Companies of New York that the third wires were put to earth at all the distributing centres and in the central stations themselves. For three years I was occupied in the construction and maintenance of the underground network of the New York Edison stations, and can state that before we put the middle wire to earth we had very frequent troubles, which, in most cases, were due to electrolysis ; in fact, not a week passed without a number of disturbances in the network, some very serious and some trifling. From the time, however, that we put the middle conductor to earth the network remained perfect and absolutely free from faults for more than three months, and it seemed as if the previously existing strong tendency to electrolytic action had disappeared. Such disturbances as did take place, at very long intervals of time, were such smaller in extent than had formerly been the case, and it was abundantly evident to us that in addition to other advantages which were obtained by this earthing of the middle wire, it was an indisputable fact that it practically freed the network from all faults, whilst no corresponding disadvantages were observed. No complaints from the Telephone Company ever came to hand to my knowledge, notwithstanding that I was in daily active communication with the officers of the Company.

The Edison central station in Boston has also since 1889 had the middle conductor put to earth after Capt. W. Brophy, of the New England Insurance Exchange, had expressed himself as follows about this earthing :—"I have carefully examined the proposal to put the middle conductor to earth in the three-wire system, I fully agree with the opinion of Mr. Edgar to which he has come after the trials made in Boston, when I had an opportunity of observing the effects. For greater reliability I think it necessary that these connections to earth should be made at many points, and whilst, perhaps, it is advisable to have such connection capable of easy disconnection, the possibility of interruption of the system through accidental mechanical disturbances or unexpected electrical influence should be avoided."

The Edison Central Station in New Brunswick, in the State of New Jersey, owns a mixed network in the centre of the town, the conductors are laid underground, whilst the external part of the town is provided with overhead conductors. It was here that the connection of the middle wire to earth was first applied, and at first simply as a protection against lightning, from the effects of which the consumers in the external part of the town had to suffer very considerably. It may be here mentioned that this connection to earth of the middle wire has proved to be a very good protection against lightning, while the advantages previously mentioned were very soon remarked. In this case the connections to earth were carried out by means of copper earth plates. On my suggestion these were taken out and examined after two years' use, and no oxidation of the same could be observed. Prof. Van Dyck of the Rutgers High School in New Brunswick, who is also a member of the Jersey State Board of Fire Underwriters, stated that this innovation in regard to the earthing of the middle wire had his entire approval, as the danger of fire from accidental earth connections is in proportion to the energy developed, the amount of which in its turn depends on the difference of potential ; it was, therefore, wise to reduce the difference of potential to a minimum, and this was practically obtained by putting the middle conductor to earth.

* From the *Elektrotechnische Zeitschrift* of October 21, 1892.

NEW EDISON-SWAN SERIES LAMPS.

In order to meet the increasing demand for series lamps the Edison and Swan Company have introduced a new form of lamp and holder, the stock sizes being 16 c.p., 32 c.p., and 50 c.p. ; the filaments are made in two sizes, for 6·8 and for 10 amperes.

The lamp is of the ordinary 3½ watt type, with very strong filaments. The terminals are constructed with thick copper lugs which conduce greatly to strength and durability. An adapter is used in connection with this in order to avoid capping with plaster which is so objectionable for large current lamps, and it affords thorough ventilation to the terminals. These are made in the Edison screw form with strong brass jaws to take the lugs of the lamp. The neck is gripped by two wire springs in such a manner that it is impossible for the lamp to fall out of the adapter, but at the same time both of these can be removed from the holder in the same way as an ordinary Edison screw lamp.

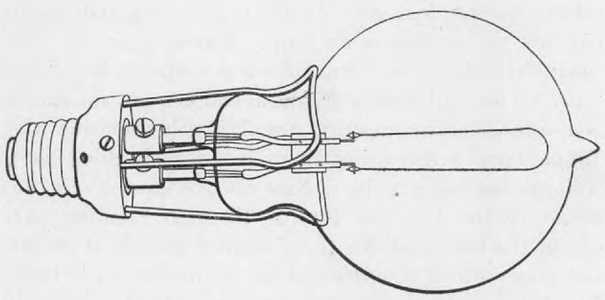

FIG. 1.—The Edison-Swan Series Lamp.

The holder consists, for the main part, of two solid brass castings fitted on to a thick fibre base ; one of these, which extends across the full width of the base, constitutes the framework of the holder and also one terminal, say the positive. From this positive terminal piece are carried up two pillars which support a thick brass ring, which in turn carries an Edison screw socket, and into this the lamp adapter is screwed. Between one of these pillars and the ring is fixed a flat spiral spring of phosphor bronze, one end of which presses against the under side of the projecting arm of the negative terminal, forming the centre contact of the holder, in such a manner that it short-circuits the holder so long as it is maintained in this position. The centre of this arm is hollow, and in it runs a pin rather longer than the contact piece, being brass at the upper end and fibre at the lower. The only excuse for using this form of insulation is

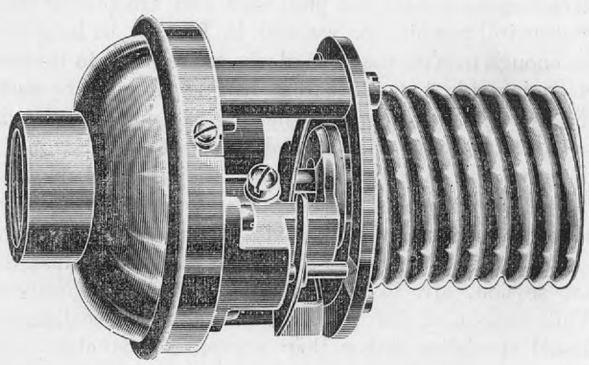

FIG. 2.—Holder for Series Lamp. Full Size.

that the lampholder becomes hot, and free ventilation being afforded, the fibre will probably be kept dry ; the insulation, so long as this condition is maintained, will be very fair. When the lamp is in the holder it will be seen that the pin is pressed down so that the phosphor spring is kept at a distance, and the current passes through the lamp instead of being short-circuited across. The other end of this spring will be seen to carry a short pin, which it causes to be pressed downwards on to the near side of the negative terminal, and between these is placed the fuse paper which, the moment the lamp ceases to act from any cause whatever, receives the full volts of the circuit, and is instantly pierced so that the current continues to flow without interruption.

In factories where arc lighting is used, these lamps would be useful for offices, and where street-lighting is carried out with a set of mains distinct from those of the general supply, these glow lamps might with advantage be employed.

LEGAL INTELLIGENCE.

Hopkinson v. The St. James's and Pall Mall Electric Lighting Company (Limited).

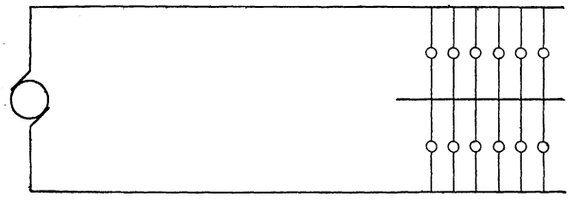
THURSDAY, NOVEMBER 3RD.

On the hearing of this case being resumed, Sir H. DAVEY made an application to introduce further evidence not mentioned in the particulars of objection. This related to several alternating current machines constructed by Messrs. Siemens. These machines were wound with independent circuits expressly for the purpose of such circuits being used in series in connection with three main conductors and lamps arranged in the same way as described in Fig. 5 of the plaintiff's specification (*see The Electrician*, November 4th, p. 7). One of these had been used by a person named Andrews, who was formerly in the employ of Siemens, and afterwards in the employ of the National Electrical Company of Glasgow, and the machine was used by the National Electrical Company of Glasgow for some considerable time.

Sir RICHARD WEBSTER opposed the application, and after some discussion,

Mr. JUSTICE ROMER decided to allow cross-examination to be taken without prejudice.

Dr. JOHN HOPKINSON, examined by Sir Richard Webster, said that he had devoted his attention for many years to the study of electric lighting, and took seriously to that class of work about 1878 or 1879. It was almost a part of his everyday business to keep himself as far as possible *au fait* with what was going on. Up to the end of 1879 or the beginning of 1880 electric lighting was always carried out by means of arc lights The arc lights were either single lights or else coupled in series. There was one exception, that was the Wedermann lamp and lamps of the same class, in which the carbons were kept actually in contact. When more lamps were put in, the potential would require to be raised in proportion to the number of lamps. With a number of incandescent lamps the current was distributed between them, and the object to be attained was to get the pressure the same at the beginning of each. By the aid of a diagram the witness then explained the matter to the Court. As a matter of fact some of the lamps being farther away from the generating station than others altered the pressure to a certain extent. A device to get round this difficulty was to take a separate conductor from the generating station, and allow that conductor

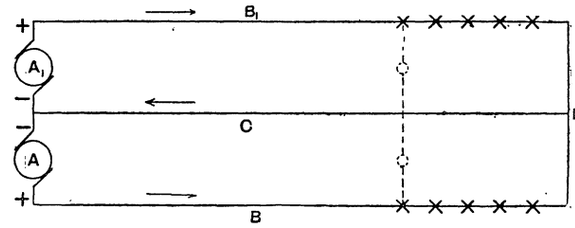


J. H. 2.

to feed in at different parts of the circuit. It was that variation of potential which occurred at the lamps at a distance from the generating station that led witness to devise his indicator referred to in the first claim. There was an advantage in using high voltage because one was able to transmit a given amount of power with smaller conductors. It was very early the object of effort to discover how to reduce the size of the conductors. Copper was a serious item in electric distribution. It ran already into many thousands of pounds in London alone. Practically speaking, glow lamps could not be made for more than a certain voltage. Looking at diagram marked J. H. 2 (*see* Figure), witness said that it represented one of the devices to enable less copper to be used, and at the same time to get a high voltage. The purpose of the third wire was to get all the lamps independent of each other as far as possible. The objection to the J. H., 2, system was that supposing they turned out one of the lights of the first group they then had too much current on one side and too little on the other. [A working model, illustrating the matter, was then put in and worked by Mr. Belfield, of the Westinghouse Company.] To make the system in question work, it was absolutely necessary to maintain absolute equality of the two sides; nevertheless, it was very largely tried. The model having been altered to represent the three-wire system, witness said that in that case the existing third wire was brought back from between the series of lamps to between the two machines. Two dynamos were substituted for one, and were connected in series. [The whole system was then explained at great length by aid of diagrams and hydrostatic analogues.] Witness was not aware of any user of the three-wire system prior to the date of his specification, though three wires had been used in connection with duplex telegraphy, which had no bearing on witness's invention. Three wires had also been used in connection with a common return in electric lighting. [A diagram marked J. H. 6 (*see* Figure), was then handed in, and the witness was examined in reference to it.] The dynamos A and A_1 were plainly not in series. There was by that arrangement no saving in copper, since the middle conductor C was merely a common return to the two outer conductors B and B_1 and had, therefore, properly to be double the size of either of them. There was also the objection that the machines were liable to reversal. Examined next in reference to the second claim of his patent, witness said it was essential to his system that the two dynamos should be placed in series. The defendants carried out the three-wire system precisely as above described. He had not, however, seen anything of the defendants infringing his first claim. [Witness next described to the Court the various devices, including his own, for ascertaining at a generating station the exact pressure at a distant point on the system.] The aim of his invention was to dispense with the pilot wires, and from an examination of the condition of a conductor at the station itself, to inform the engineers what was happening at a distant point. The drawing and the letterpress would enable a competent workman to construct this improved voltmeter. The witness stated that he had carefully examined the six anticipations which were enumerated in paragraph 6 of the particulars of objections, and was of opinion that none of the apparatus would do unless modified to a certain extent, and the application was absolutely and completely distinct.

Cross-examined by Sir HORACE DAVEY,

WITNESS stated that the three-wire arrangement was for the purpose of enabling two lamps to be used in series on a parallel system, so that every lamp could be turned out independently of every other. The system was applicable to arc lighting in the sense that one could use it, and did now use arc lamps in parallel upon the system. Arc lamps were really used as an accident to incandescent systems, though no doubt a saving of copper would be obtained.



J. H. 6.

Sir HORACE DAVEY: Now will you tell me anywhere in your specification in which you have pointed out or stated, or in any manner told the public that your system is to be used with incandescent lamps only? I do not find any or else I would put them to you.—I do not know whether it does or does not, really.

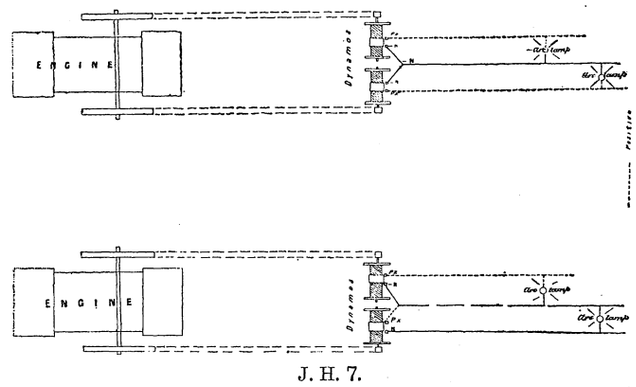
Sir HORACE DAVEY: If my learned friend can refer to any passage in which incandescent lamps are referred to I shall be glad.

Sir RICHARD WEBSTER: As you ask me to do so, I will refer you to page 5, line 20; but there are several other passages.

WITNESS: Yes, there it is: "When special circuits are required for specific purposes, or for charging secondary batteries, or for arc lighting, in addition to the ordinary incandescent lighting."

Sir HORACE DAVEY: But that relates to the first part of your invention. I now take it that from the beginning to the end of the description of the three-wire system in this specification there is no mention of incandescent lamps.

The Witness was next examined with regard to the system by which two circuits are used with a common return. He admitted that if the polarity of dynamo A in J. H. 6, were reversed and two lamps placed as shown by the dotted lines, these lamps would be in parallel on the united circuit, and if similar pairs of lamps were similarly arranged elsewhere on the circuit, the arrangement would be tantamount to the three-wire method. If, however, the lamps so placed were arc lamps, there would be no particular advantage gained, and, indeed, as compared with the ordinary series system of arc lighting the amount of copper used would be large. Moreover, he very much doubted if in 1882 there were arc lamps which would burn economically in parallel; his impression was that such lamps were a recent improvement.



J. H. 7.

Mr. JUSTICE ROMER: Let me ask a question so that I may understand. Suppose your system was applied to arc lighting. What do you say; would it be useful for that? Do you say it would not be useful?—I say it would not be useful in comparison with other ways of doing the same work. It would be useful in comparison with a system in which you have the whole of the arc lights arranged in parallel, but that was not the usual way of arranging arc lights at that time. The almost universal custom was when more than one was used to arrange them in series.

Witness was next examined with regard to the installation put up by Mr. Crompton's firm, and worked for many weeks, for the purpose of lighting the Alexandra Palace in 1880 and 1881 (*see* diagram J. H. 7, of the connection of this installation).

Hosted by Google

After explaining the meaning of the diagram to the Court, witness stated that supposing that it was proved to the satisfaction of the Court that that was what was done for the purpose of lighting the Alexandra Palace in the winter of 1880 and 1881 it would not be an anticipation of his three-wire system. It would not be within the claim at all. Because there were here no lamps in parallel and the dynamo was unsuited for working lamps in parallel at all. The Alexandra Palace network, moreover, was not a system of distribution, *i.e.*, a system in which you supplied a current to a diversity of consumers. It was perhaps a system of supply to various points.

Sir HORACE DAVEY: Is it or is it not an essential part of your patent that there should be feeders separate from the supply wires?—No, but it is essential that the system should be such that feeders would be applicable to it.

Witness was then examined at length upon his specification, and stated that it was not necessary to have the third wire of the same dimensions as the two leads, though it would be equally a third wire if it were the same dimensions; but they would not then realise the full advantages of the invention.

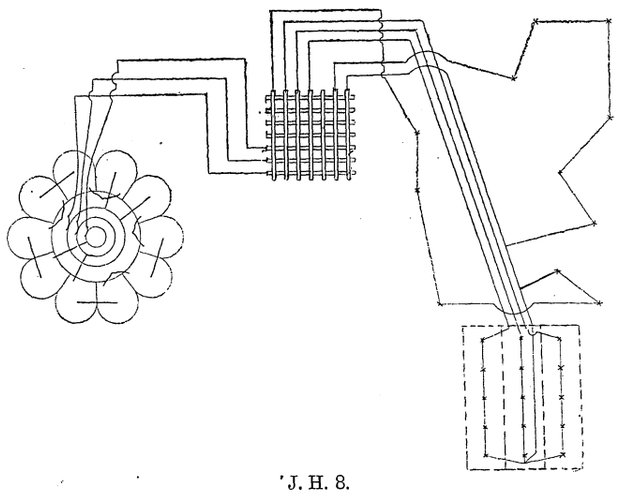
At this point Sir HORACE DAVEY addressed his lordship with regard to an affidavit of Mr. Curtis Hayward, solicitor to the defendants, with regard to the introduction of fresh evidence of anticipation.

Sir RICHARD WEBSTER submitted that the affidavit was wholly insufficient for the admission of the evidence, at any rate in that stage.

In conclusion it was decided that Sir Richard Webster should be given particulars of the objections.

Dr. JOHN HOPKINSON recalled and further cross-examined by Sir HORACE DAVEY at great length with regard to the equivalence of a single arc lamp to several incandescent lamps and the utility of the common return in an installation such as that at the Alexandra Palace.

Sir HORACE DAVEY: Supposing I had two arc lamps in series on each part of each division, and put out one, then would not it operate?—What would happen then would be that you would get a greater current on the side on which you had one lamp, and you would get a greater current passing back again down the middle conductor, but again would have a worse arrangement than if that middle conductor were not in use because you would have the lamp with such an excess of pressure upon it that it would burn exceedingly bad.



J. H. 8.

My witnesses do not agree with you there; they think it would be highly beneficial.—Well, I am sorry.

There is nothing for my learned friend to laugh at. I am instructed by gentlemen of position, who will be called before your lordship, who do not agree with Dr. Hopkinson. It is not a crime not to agree with Dr. Hopkinson. Now I will ask you this: It is desirable, I think you told my learned friend, to increase the electrical force in your mains?—Yes, on account of being able thereby to diminish the size of the conductors.

In point of economy?—Yes.

And by the use of this third wire system with arc lights you do get that advantage?—You get no advantage as regards economy in comparison with burning two lamps in series without a middle wire at all.

Will you point out any other place in the specification where you confine your third wire system to lamps or electricity consuming appliances arranged or parallel?—Yes, you put me on the whole specification.

Show me where it tells the public so?—To begin with you have a fixed potential in the very first two lines of the specification.

But that is the regulator?—Undoubtedly, it is a part of the patent.

Is there any mention of the parallel arrangement there?—No, but it is absolutely implied by the fact that you have to keep a constant pressure.

It is implied by the fact that you have to keep a constant pressure and that is all you would say.—I say it is absolutely implied and will not apply to anything else, and was never intended to apply to anything else. I say the words I there use imply a parallel system and they are not applicable to a series.

Do you suggest to me that you cannot use lamps in series on a fixed voltage system?—No, nobody ever would use them so. The two systems are broadly distinct and the words used here all the way through this specification are applicable alone to a parallel system and are not applicable to a series system.

There is no direction in your specification that when alternating currents are used in this way the dynamos are to be rigidly connected, or to have a common axis?—No, nothing whatever.

Did you ever have any experience prior to the date of this specification of any person having worked two or more alternating dynamos in series?—I do not know that I have.

Can you refer me to any text-book or paper on the subject that I can refer to showing that it was common knowledge that alternating dynamos should be coupled rigidly?—I do not know that I can; but I do know that when there were two alternating current dynamos used for the purpose of lighthouse illumination in order to give you a double current they were rigidly connected.

And your patent does not contain any direction for the use of mechanical gearing where two alternating dynamos are to be coupled in series?—No, it does not. I never dreamt of putting it in.

Supposing you have two alternating dynamos coupled on the same common axis, that is, in fact, the same thing as one dynamo double wound.—Yes, it comes to the same thing.

The Inchicore system was made by Messrs. Siemens, was it not; and in that system you have one dynamo fitted with two coils, and that would be the same thing as two dynamos arranged in series? Assuming this to be a correct diagram (*see* accompanying figure, diagram J. H. 8) of the Inchicore machine, do you not find in this machine a third wire system similar to yours?—You find a third wire going up to the switchboard, and then on the switchboard you have not indicated what the connections are to be.

Does not that outside wire going from the switchboard perform the office performed by your third wire in your specification?—No, not strictly speaking.

It would operate as a means for carrying off excess or supplying deficiency?—Yes, exactly the same as before—that is to say, in my view, at all events, it would act injuriously. There is another advantage which is secured by the presence of that wire, and that is, that you can burn five lamps, and leave the other five lamps out without going round to turn them off.

Assuming that in the opinion of the Court your specification, according to its true construction, is applicable to arc lights, and applicable to lamps arranged in series, is there any difference between this diagram, supposing it to be a true diagram of the Inchicore installation and your specification?—Assuming that my specification applies to this arrangement in which any utility is totally different from that which I intended, that would be so.

WITNESS was next cross-examined as to whether the mutual induction of the two coils of his regulator-galvanometer and the induced Foucault currents in the core would not when used on an alternating circuit interfere with its working. Witness thought practically not, but stated that he had not tried the matter experimentally. As a matter of fact, the Westinghouse Company used it themselves, though not pure and simple. He was not aware of any at work without improvements. He was not, indeed, aware of any place in this country where it ever had been put into operation. The essential feature of his regulator was the employment of a differentially wound indicating or regulating apparatus, so connected to the conducting wires from a generator of electricity to a distant place as to indicate when the difference of potential between the two conductors leading to such distant place deviated from an assigned value at that distant place, or to regulate the electricity producing machinery in such wise as to maintain a constant difference of potential at a distance from the place of supply, or generation of the current. The existence of series and shunt coils in one apparatus was already well known for the purpose of regulation. Abdank had proposed the combination of those two coils for a totally different purpose. If they used Abdank's instrument as he intended it to be used it would not answer the witness's purpose. If they used the witness's instrument in the way Abdank intended it to be used it would not answer the witness's purpose. The regulator certainly would not require improvements to work either with continuous or alternating currents, but for alternating currents it was convenient to make some improvements in it.

After re-examination by Sir RICHARD WEBSTER, the Court adjourned until Friday.

FRIDAY, NOVEMBER 4TH.

On the Court resuming the hearing of this action, Dr. JOHN HOPKINSON was recalled and further re-examined by Sir RICHARD WEBSTER.

WITNESS stated that, speaking of his specification as directed to a workman, it would not lead the workman to establish a system of arc lighting without incandescent lights. Arc lamps might be used in parallel as an incident, but it was very difficult to use them on a parallel system. As described to an electrician, there was in his invention a distribution of the current amongst different consumers. In 1882 the regulators of arc lights were not sufficiently good to enable them to run in parallel in a really satisfactory way. Until very recently a very considerable resistance had to be added to each arc light in order to keep it steady; but the regulators of late had improved so much that the resistance might be reduced to a comparatively small amount, even to-day no one would for choice run arc lamps in parallel. If one only required to have arc lighting one would not get the advantages which were mentioned in his specification, and even to-day when a large number of arcs were required, people always put down special plant for running arc lights in series. It would be absolutely clear to anybody that every one of the lamps in Fig. 5 of the specification was intended to indicate an incandescent light. The bulb and the continuous filaments were shown in every case. In diagram J. H. 7, assuming that both arc lights were burning there was no advantage in the lower sketch in the middle wire. There was no difference in the wiring between J. H. 8 (Inchicore) and J. H. 7 (Alexandra Palace), except that in Inchicore there were five lamps in series as distinct from one lamp in J. H. 7. The middle wire in J. H. 7, was only of use if one wished to burn only half the lamps.

Hosted by Google

One of the merits of his invention was the great saving in copper. The use of the middle wire in J. H. 7, saved no copper at all, unless they took it as being equivalent to putting in two circuits instead of one. As to feeding mains on a simple arc system, he did not see how they could get them in. The title of the patent was "Improvements in distributing and measuring electricity, and in apparatus to be employed for that purpose." Nobody would describe an arc system as a system of distributing electricity.

LORD KELVIN was then sworn, and examined by Mr. ASTON: Witness stated that the title of the specification "Improvements in distributing and measuring electricity and in apparatus therefor," would convey to him the meaning "of causing to diverge into different groups the electrical energy supplied from a central station by mains." At the time of the inquiry before a large Committee on electric lighting, in 1879, it was shown that there was then a great want for what was called the distribution of electricity. The arc light was the only kind of electric lighting that was known at the time, and many questions were to put to various witnesses as to discoveries that could lead to the distribution of electricity. It was rumoured that Edison had such a discovery, but to the best of his recollection nothing definite regarding it was put before the Committee. The text of the specification, coupled with the drawings, described the three-wire system with perfect clearness and without any ambiguity of any kind, As regards the regulator, witness was of opinion that the directions with regard to its use with alternate currents were quite sufficient. In his opinion the three-wire system as described by Dr. Hopkinson in his specification was certainly new in July, 1882, and very useful indeed. It really made the difference between electric lighting being possible on the low-pressure alternate-current system, and almost impossible on account of the expense for copper. Mr. Abdank's invention and specification did not disclose anything that could lead towards the achievement of the object of the first part of Dr. Hopkinson's invention.

Cross-examined by Mr. FINLAY, Q.C.,

Witness stated that the multiple-bridge system of course was not part of the invention. The merit of the invention was the application of a third wire to a point intermediate between the positive and negative extremes of two dynamos in series.

Mr. FINLAY: Is not what you regard as the merit of this invention, the application of a third wire, connected in the same way as in those two diagrams, the Inchicore and the Alexandra Palace, to a system of multiple arc lights?—It could not have been of any practical use in a system of multiple arc lights, because multiple arc lights would naturally be put in series.

Is it not substantially the three-wire system as in this patent?—It is the three-wire system applied to two arc lamps.

Let me suggest what is put to me as one advantage of the third wire as applied to arc lamps. If you had two arc lamps in series in the way delineated there, not being provided with shunt regulators, would not the application of the third wire enable those two arc lamps to be burned in series when they could not have been burned in series without it?—Yes, I think it would.

That is to say, that the application of the third wire in that way would dispense with the necessity of the shunt regulator in the arc lamp?—It would dispense with the necessity for a regulator by which the circuit might be broken through an arc lamp.

In continuation of his cross-examination, witness stated that the use of the third wire in application to such a system with two arc lamps in series might affect a considerable saving if the distance were considerable, but the saving would be less appreciable with more lamps on. The third wire would only be an encumbrance for such a case as 10 arcs in series. Gülcher had a large dynamo that was intended to run in parallel, and if he had a lamp fitted for it it was probable he had an appliance by which they could be got to run parallel, but nobody in their senses would dream of using such appliances in connection with arc lamps either then or now, unless a number of arc lamps had to be placed on a circuit already provided for incandescent lamps. As to the Crystal Palace parallel circuits, unless the lamp were very close to the dynamo they would be very uneconomically arranged. He did not wish to say anything against the machine, only he must say nobody in their senses would dream of arranging a large distant circuit of arc lamps on that system.

Re-examined by Mr. MOULTON: Supposing that you take the system shown in Fig. 5 of the specification, and supposing instead of that incandescent lamp a couple of arc lamps were put in series, would that system be the system seen in Inchicore or in the Alexandra Palace?—No, I think not.

Would it still be a system of parallel bridge?—It would be still a system of parallel bridge.

Further cross-examination by Mr. FINLAY: If you are working on a system of alternating currents, would not the effect of that arrangement with alternating currents be this, that the current in the thin wire of the regulator would set up in the thick wire by mutual induction a considerable current?—Quite an infinitesimal current relatively to the whole current of the thick wire; but infinitesimal, or not infinitesimal, it would be allowed for when the adjustment is made by the experimental method which, in line 10, page 5 of Dr. Hopkinson's specification, is said to be the more practicable method. The experimental mode of adjustment would meet all the mutual indirections to which reference has been made.

Mr. MOULTON: You have had very great experience in galvanometers, differential and otherwise, have you not?—Yes.

In your opinion, are the directions sufficient to guide a workman, whether he is making it for an alternating system or a direct system?—Yes.

The next witness called was Mr. REGINALD BELFIELD, of the Westinghouse Electric Company, who was examined by Mr. ASTON.

Will you look at the diagram which has been put in marked J. H., 7, do you find there an employment of the three-wire system described in the patentee's specification?—No, I do not.

Why not?—Because there are no lamps arranged in parallel there. Everything is in series.

Witness concurred with Dr. Hopkinson and Lord Kelvin in regard to the inutility of the third wire in the Alexandra Palace installation, and on other points. He agreed with the statement made by Lord Kelvin that the directions given in the specification, in the general terms in which they were given, were sufficient with regard to the use of alternating currents. He saw no application of the three-wire system at the Crystal Palace Exhibition in 1882.

Cross-examined by Sir HORACE DAVEY.

WITNESS stated that the double-coil armature of the Inchicore dynamo differed from the pair of dynamos referred to in the specification, because in the pair of dynamos referred to in the specification each dynamo could be separately regulated, and one could therefore preserve a constant difference of potential at the lamps.

Sir HORACE DAVEY: If I made a draught upon your imagination and asked you to imagine an installation in which there were six houses lighted, or a dozen houses lighted—six in each division, as in Fig. 5—suppose all the six houses in one division put out, and suppose five of the houses in the other division are not burning. Then the current would pass through only the lamps of the house in which the light was left burning, would not it?—Yes.

And after passing through that it would all go down the third wire?—You would simply have a two-wire system then.

Mr. JUSTICE ROMER: Just answer the question. You see you are here to give assistance to the Court. You must not be too much of a partisan.

Sir HORACE DAVEY: The Westinghouse Company are proprietors of this patent?—Yes, I believe so.

I am not making any complaint of Dr. Hopkinson being plaintiff; I am very glad to see Dr. Hopkinson at any time, but all the beneficial interest in this patent is vested in the Westinghouse Company, in which you hold the position of head electrician. Now this state of things would be exactly what you have described with reference to the arc lamps when one arc lamp is left burning in one division, and all the other arc lamps in the other division are put out, would not it?—Yes.

Can you tell me any instance in England where the regulator has been used?—Yes, at Sardinia-street, Lincoln's Inn-fields.

Is it used exactly as it is described in the specification, or with additions?—It is used in a modified form. A transformer has been put in to reduce the voltage to allow it to be worked conveniently, and instead of the two coils being wound on the indicating device, it is there wound separately on a smaller transformer and the indicating device is separate.

Did you make those additions?—No, Mr. Shallenberger, the Chief Electrician of the Westinghouse Company in America, made those additions, and I experimented with them and found them successful.

In every place where it has been put up in any of the States it has been with those additions?—Yes.

Mr. Schallenberger, I think, took out a patent for his additions that you have mentioned, did not he?—Yes. An English patent.

I have been told—I do not know whether that is correct or not—that dividing the iron core would get rid of the Foucault currents but not get rid of the induced currents?—All I can say is that as far as my experiments went we never had any difficulty with that at all.

I think this is the first action you have brought on the third-wire system?—It is.

But we are not the only persons who use the third wire without paying royalty?—Well, no, I think there are other people who are using it. I think that you are about the first we have heard of who are doing it and who are not paying royalty.

Re-examined by Mr. MOULTON, witness stated at the date of the patent transformers were not used as a means of distribution. It would not be convenient to use a thousand volts in a differential instrument.

Mr. JUSTICE ROMER: In other words, the modifications or additions you speak of were only to meet some special circumstances?—To meet special circumstances.

Continuing, witness said that he did not consider in the case of distribution by parallel arc the case of all out on one side and all alight on the other worthy of consideration.

Sir FREDERICK BRAMWELL was the next witness called, and was examined by Mr. HOPKINSON, Q.C. Witness stated that the suggested anticipations in the case did not solve the problem of cheap electrical distribution. When they had a series system, the third wire was no use as long as the whole concern was working. In his opinion the regulator was a useful invention, and could be adapted to an alternating machine.

Cross-examined by Sir HORACE DAVEY: With all your great acquirements, Sir Frederick, I take it that you are not yet an electrical engineer?—Well, I thought I was.

Is it within your knowledge that in South Kensington the arc lights in large number are arranged in parallel on the system?—Yes, I do not think in large number, but it is within my knowledge that arc lights are arranged in parallel on the incandescent lighting system—on the three-wire system.

After re-examination by Mr. MOULTON, the learned JUDGE intimated that he would at that stage like to hear the argument of plaintiff's counsel on the question of construction of the specification.

Sir RICHARD WEBSTER: A suggestion has been made, which took the plaintiff's advisers by surprise, that the specification can be construed as enabling a person to make a system of arc lighting, and to include in the claim a claim for the system when applied to arc lights in series. We had no reason whatever to anticipate such a point being raised for the defendants. Now, we contend that upon the true construction of this specification it would be unfair to the plaintiff to construe it as pointing to arc lighting alone, or including in the claim a claim to using his system alone with lamps in series.

Hosted by Google

Mr. JUSTICE ROMER : The point is—does it cover, that is include, in the claim a case in which there are nothing but arc lights.

Sir RICHARD WEBSTER : If it means that an arc lamp may be substituted for an incandescent one, then we do not dispute the proposition. We contend that the only point is whether it covers a claim to series lighting, whether by arc lamps or any other which are not arranged in a multiple parallel bridge. The distinction is not one between arc and incandescent lamps, but between an arrangement in parallel or in series. We protest against the specification being construed so as to include "series," as distinguished from "parallel." We must go back and read the specification as it would be read in 1882 with the knowledge men possessed at that date. Remember what the evidence on this point is—that series lighting by arc lamps was well known. It is not suggested by Sir Horace Davey that anyone would speak in 1882 of an arc light system being a system of "distribution." That term meant that the current was "distributed" in being led from one conductor to another. To determine the nature of the invention, we must look at the provisional specification. Its title reads as follows:—"Improvements in distributing and measuring electricity, and in apparatus to be employed for those purposes." It must be both distributed and measured. The evidence is to the effect that no competent electrician would have spoken in 1882 of an arc series as being a system of "distribution." The specification continues—"My improvements principally relate to maintaining the electromotive force on a system of conductors for an electric supply at a fixed potential." Here the patentee tells the public that his improvements relate to maintaining a "fixed potential," one does not desire and cannot have a fixed potential with lights arranged in series.

Sir HORACE DAVEY : You cannot use the provisional specification for construing the complete.

Sir RICHARD WEBSTER : Yes ; in *Bailey* v. *Robertson* it was decided by the House of Lords that one must look at the provisional specification to ascertain the patentee's intention. I never sought to use it for interpreting the complete. But I am entitled to say this : If the provisional has one ambit, and the complete a wider one, the patent may be good for the narrower ambit. It was so decided in *Bailey* v. *Robertson*, and that proposition has been good law ever since. For 50 years we have been told by the House of Lords to refer to the provisional specification for the nature of the invention. But as Sir Horace objects I shall go to the complete specification, reserving my right to refer to the provisional in reply. I will refer to the same language in the complete. But I submit that when the other side try to say that the complete means something else, then you are bound to refer to the provisional. No electrician can say he would read "conductors for an electric supply at a fixed potential" as referring to arc lighting. In a series system of arc lighting there is no fixed potential, in a parallel system of incandescent lighting, there is a fixed potential. But to continue : "When electricity is delivered by means of a pair of conductors to a distance from the station where the electricity is generated, there is a fall of potential due to the resistance of such conductors greater as the current is greater, and if it be desired to maintain the potential constant at the delivery end, it is necessary to increase the potential at the supply end, as the current increases, in a suitable manner." These remarks cannot possibly apply in arc lighting. In the multiple bridge system the more parallel bridges there are the larger the current required at the same potential, whereas in arc lighting the contrary is the case, the same current is required but a higher potential when more lamps are added on. Further down in the specification we read that the engine is to be regulated "for the purpose of keeping the potential on service main conductors constant." Now, no fair-minded electrician in 1882 could for a moment suppose that this expression referred to arc lighting. Nay, we go further. There is no book which contains any statement to support such a theory as that contended for by the defendants; their particulars of objection contain no reference to this matter. Now, however, they avail themselves of the fact that owing to recent improvements, long since 1882, arc lamps can be put on a parallel system. In describing how the cost of conductors is to be saved, the patentee says he places the two systems of "lamps or other appliances consuming electricity of approximately equal capacity also in series." Here he means that the quantity or volume of current required by the lamps on one side of the middle wire should be approximately equal to that required by those on the other side. The writer continues : "A main conductor is taken from each extreme pole of the two dynamos, and a smaller conductor from between the two dynamos to points between the two systems of lamps." He here indicates that it is to be joined to various points, more than one, and therefore cannot cover the case of a simple series of arc lights. Omitting the description of the voltmeter, further down we come to this passage : "For each machine I provide a pair of feeders of a size appropriate to the current they are to carry, but independent of the distance they have to go. Each pair of feeders goes to, and is connected to some part or other of the system of distributing mains, and by the use of my invention I am able to keep the difference of potential constant at, or near, the point where the feeders join the distributing mains." We do not hesitate to say that in 1882 the use of "feeder" conductors to arc lighting systems was unheard of, and, indeed, was an absurdity. Why are they used now ? To take energy without draft to where it is required to be used. Applying to that passage ordinary electrical knowledge (eliminating from consideration the improved arc lamp, which can be substituted for an incandescent one in a multiple parallel bridge), we say it cannot possibly refer to anything but the multiple parallel bridge. But that is not all. "By using a sufficient number of feeders I am able to keep the potential throughout the distributing mains very nearly constant, however the consumption may vary, without requiring conductors of excessive size"—a passage which is all absurdity if applied to arc lights. No one would even think of "feeding" a "series" system. There is only one reference to arc lighting in the specification, and that is where the patentee refers to Figs. 3 and 4, and writes : "When special circuits are required for specific purposes, as for charging secondary batteries, or for arc lighting in addition to the ordinary incandescent lighting." Again, "The intermediate conductor may be of much smaller dimensions than either of the other two, as it has only to carry the difference of current consumed by the two divisions of consumers." There can be no "difference of current" in the case of arc lights arranged in series. The three-wire system is referred to as being shown diagrammatically in Fig. 5. I hope for the sake of his reputation that there is no electrician in Court who would say that Fig. 5 could possibly refer to arc lighting. Every lamp in that diagram is connected only with two of the three wires. The only possible way of making it include arc lighting is to take out an incandescent lamp and put an arc lamp in its place. That, however, would be within the meaning of the patentee. Anyone who puts an honest construction on this specification must say it applies only to the multiple parallel bridge. The improvements which are disclaimed also support our view. The meter is quite immaterial if we are dealing with arc lighting, also the switch. In fact, if honestly construed, there is not a line in the whole specification to support the defendants' contention. The fact that at the present date there is an improved arc lamp which may be substituted in the multiple porallel bridge for an incandescent one has, of course, nothing to say to the point now under discussion.

Sir HORACE DAVEY, Q.C., then opened the case for the defendants. As to this question of construction of the specification, the plaintiff's counsel say they were taken completely by surprise. That is a mere rhetorical argument. Sir Richard himself read the particulars of objections, and his clients have seen the installation at Inchicore, hence they must have known what the defendants intended to say, and will say, is the true construction of the specification. Whatever Dr. Hopkinson may say, or whatever may be the most useful mode of applying this invention, or whatever meaning he intended to attach to this specification, there will not be found a single phrase or word in the whole of it pointing to its being confined to incandescent lighting or the parallel system. On the other hand, it is apparent from the language the patentee has used that he intended to include within his net "all lamps or other appliances consuming electricity." There is not the slightest hint of its being confined to lamps of a particular character ; on the contrary, we are told it is applicable to any system or appliances which consume electricity, including within that description, of course, "any lamps." We submit that the language of the specification is such as would enable him to sweep into the ambit of his patent the three-wire system when used in connection with arc lighting as well as the incandescent multiple bridge. What would have been easier than to say what the patentee now alleges he meant to say. No doubt he intended to include all applications within his patent, although in the case of the multiple arc of incandescent lamps there is more benefit to be got from his invention than in others. Now assuming, for the sake of argument, that we prove that the defendants in fact used the three-wire system with arc lamps and with arcs in series, what was there to prevent them from applying a well-known mode to another system ? Sir Frederick Bramwell said in the box that they would have to make certain material alterations, but they would have to do that in adopting the incandescent system. How could the patentee prevent them from doing that which they could, apart from his patent, have done before ? They have it for arc lamps and use it, they then change to multiple parallel bridge, they alter their conductors without the plaintiff's aid, they already have the dynamos, conductors and three wires. If my friend's contention is right as to construction of specification, then the objection is really want of subject-matter. The plaintiff's patent would prevent the defendants from changing their mode of lighting as they might otherwise do, and all the world knew how to do. The plaintiff, in fact, says : "I have taken out a patent, you cannot therefore make that change!" which is after all only telling the defendants the most useful way of employing the three-wire system which they already had. Now we shall criticise the language of the complete specification a little more closely, when it will be seen that, from inadvertence no doubt, the patentee now gives it a meaning that it will not bear. One is surprised to hear from an ex-Attorney General that one could use a provisional specification, when there is no question of nonconformity, to aid the Court in construing the complete.

Mr. JUSTICE ROMER : He meant that when you are in doubt as to the meaning of the complete you are entitled to look at both together, to ascertain the real meaning of the complete and narrow it. He never said this could be done when both were clear.

Sir HORACE DAVEY: The provisional specification describes the nature of the invention and the complete the way of carrying it out. Now that I have read the provisional more carefully, I do not think it carries it any further. There is no difference between the two. Plaintiff's counsel suggests that "distribution" has a technical meaning confined to the multiple parallel bridge. It is a well known word in the English language, and the plaintiff used it just as he pleased. In the claim he makes it synonymous with electrical supply, he advisedly used larger language in order to draw as much fish as possible into his net. The specification commences with the passage already read by my friend, which relates to "maintaining the electromotive force. . . at a fixed potential," and to "reducing the cost." Now it may be that there are two distinct inventions, one for regulating or indicating the potential, or difference of potential at distant points, and the other for reducing the cost of conductors consistently with efficiency and safety. This is an odd argument. You only want to ascertain that the potential at the lamps is equal in the case of the parallel arrangement (conceding that for the moment), *ergo*, says my friend, the first part of the invention will only apply to the parallel arrangement, *ergo* the second part, which is equally applicable, is applicable now only to the parallel arrangement. That is my paraphrase of his argument. We deny that in 1882 the instrument described for ascertaining the potential would only be useful for the parallel system, and that the

Hosted by Google

parallel system *only* can be meant. A person may mention an instrument for one purpose, yet it may be useful for another, namely, to measure the potential at a distant lamp in an arc series also. If anyone so employed it it would be covered by the claim. The patentee makes a claim for the regulator itself, and not merely for the use of it. The term "conductors for electricity" cannot, therefore, be cut down to refer to one class only. My friend says that the term "such conductors" must mean only those with a fixed potential. That is not the context, and it may be read the other way. There is nothing which confines that expression to electric supply in a parallel bridge. The words disclaimed refer to an arrangement for disconnecting the dynamos from the conductors. No one could pretend that it referred only to a parallel system, for it is equally applicable to every conductor and dynamo. The patentee describes an instrument, which seems a very efficient one for measuring quantity of current in any system of conductors. That is the very thing that is wanted in a series system. Next the differential galvanometer which he describes is the first invention; the two are perfectly distinct. The regulator for measuring potential may be usefully employed for other systems as well, although they say it is only useful now for a parallel system. What is claimed, however, is the instrument itself, apart from its application to any system. Now to consider the second invention. Edison's lamp was invented in 1879, and Swan's in 1880. Two years afterwards their value was appreciated, and incandescent lighting became a practical success, so that when this specification was written, men's minds were only beginning to be directed to the subject of incandescent lighting. The best known, and till then the only system, was that of arc lighting. If the patentee was going to tell the world this, "Incandescent lighting is only now a success, I am now going to give you a means of lighting by incandescent lighting in parallel or multiple arc, which will apply Edison's invention to a practical and particular use," he carefully abstains from confining it to what it is now alleged to be confined to, but speaks of it in connection with "other appliances." He goes on to say, "For the purpose of economising the cost of main conductors," not in a parallel system of incandescent lighting, but "main conductors," used in its largest possible sense. And then continues, "I place two dynamo machines in series, and I place two systems of lamps," not "two parallel systems," but "two systems of lamps," and so sweeps in every lamp, not to speak of "other appliances," which are to be placed "also in series." We say this specification is not confined to the parallel system. If we cannot contend that then we say it is bad on the ground of ambiguity. All we are told is that the lamps are "also in series." That would include all the rungs of the ladder. What is there to confine it to one rung only? Again, "A main conductor is taken from each extreme pole . . . and a smaller conductor from between the two dynamos . . . serving to bring back to the central station any electricity required for one system of lamps in excess of that required for the other." My witnesses will say that this passage is equally applicable to one system as well as to the other.

At this point the Court adjourned until Saturday.

SATURDAY, NOVEMBER 5TH.

Sir HORACE DAVEY: When your lordship rose yesterday I was commenting on the language of the specification, because, after all, that is what we have to look at—the meaning of the patentee as expressed in the specification. I had just pointed out that the patent is not confined to two systems of incandescent lamps, or two systems of lamps, but applied to other appliances such as for example electro-motors. I had pointed out that the patentee, although he mentions that the lamps are to be in series, does not mention that they are to be a part of a parallel arrangement. Suppose electro-motors were placed in series, and it is required to do a particular amount of work or "load," let one motor be 2 H.P. and the other 1 H.P., the third wire would conduct the extra current. Such a case as that comes clearly within this passage of the specification, it is not at all confined to incandescent lighting. The real truth is, which we concede, that the patentee had chiefly in his mind the case of incandescent lighting; but like many patentees—in fact, like most—he has endeavoured to make his claim in such large terms as would comprise arrangements other than those he had in his mind. When one comes to attack a patent, the patentee on his defence seeks to put a narrow construction on his specification. If it were a case of infringement and a person used two electro-moters in series, such as I have described, would not Dr. Hopkinson say that it was an infringement of his patent? That question of infringement would not be arguable, for you would have in the words of the specification "two systems of lamps or *other appliances* consuming electricity of approximately equal capacity also in series." The specification continues: "More than two dynamos may be placed in series, and more than one intermediate smaller conductor may be used on the same principle as above described." With this passage this part of the case ends. So far as the general description goes and the "nature of the invention" there it ends, the part corresponding to the provisional. We submit that, so far, there is no reference whatever to its being confined to the parallel system alone. The next portion was struck out on amendment. We must now construe the specification as it stands. The patentee next goes on to describe his invention by reference to the drawings. He shows that his object is to keep adjusted the factor E−CR, so that the pressure at the houses be kept constant. The next paragraph describes the construction of the indicator or regulator, and the following one is important, for he says there "the application of this instrument to an *extended system* of electrical supply with a network of distributing mains is important." Lord Kelvin, in his evidence, seemed to infer that the word "distribution" had a technical meaning, and was to be confined to the case of incandescent lighting in parallel arc. We do not at all agree with that view. The word "distributing" was perfectly well-known to refer to simply bringing it to customers and consumers. To take a homely illustration—the milkman "distributes" milk in his morning rounds. He goes his rounds "in series." I am told that numerous examples can be shown in text-books of "distribution" being used in the wider, that is the popular, sense of bringing the supply to places where it is to be consumed. But it is not necessary to dwell further on this, for the patentee thought the narrower construction might be put on his specification by some people, so in his claim he takes care to avoid such a result. He there says, "electrical distribution *or supply*." No one suggests that the word "supply" is not wide enough. In fact Dr. Hopkinson, in his evidence, agrees with me that the word "supply" had no technical meaning. Next follows the description of the regulator, and as to its application the public are told, "When special circuits are required for specific purposes, as for charging secondary batteries, or for arc lighting in addition to the ordinary incandescent lighting, such special circuits may be prevented from disturbing other circuits," &c., that is to say, that when a particular use is to be made of this regulator it may be adopted or adjusted to meet the circumstances of that particular case. This passage relates exclusively to the regulator. It is idle to suggest that a passage relating exclusively to the first invention has any bearing whatever on the construction of words describing the second invention. Moreover, it shows that the patentee had in his mind the difference between incandescent and arc lighting, and the different conditions of each. If he has not, when describing his second invention, described it with reference to one or other system, there is cogent evidence that he wanted his claim to be as wide as possible. The patentee next goes on to describe with reference to the drawings of his second invention. We do not say that Fig. 5 does not represent a parallel arrangement. But he must in a diagram take an instance, either parallel alone, or series alone, or a combination of both. One cannot make a picture of a "general" case. It was the parallel arrangement that the patentee had chiefly in view, and therefore he showed it in the diagram. The question is whether the *words* of his description are not such as go beyond and include other cases besides the arrangement in the illustration.

Mr. JUSTICE ROMER: The question really is, Is the specification, according to its true construction, confined to the parallel system or not?

Sir HORACE DAVEY: If the patentee meant so to confine it, why should he not say so? Nothing would have been easier. For the purposes of illustration he gave the case of houses because that application of his system was clearly in his mind. Again, he says the intermediate conductor "may be," not *must* be, of smaller dimensions. We shall prove in our anticipation that it was, in fact, smaller, but the patentee merely shows he had a preference.

Mr. JUSTICE ROMER: They say that the middle wire only carries the difference of current, which is the main feature, and that in a series arrangement there is no difference of current to be carried. Enlighten me on that point.

Sir HORACE DAVEY: To that question I have three answers:—(1) Exactly the same observation applies to incandescent lighting. It is quite possible that all the lights be put out in one division. That may not be likely in a large system, but where it is applied to a small system it is quite possible. (2) It is not true with arc lights. The same thing occurs exactly as with the other system. (3) Arc lamps do not burn uniformly. The carbons tend to move apart, resistance varies, so that there will always be a small current in the centre wire. But for the purpose of construing this specification, I am not bound by the instance of arc lighting. Take any other electrical consuming appliances, say, electro-moters, one a 2 H.P., another 1 H.P., without the third wire the whole would go through both. The balance goes down the centre wire. No one will say that in the case of two motors this invention will not be very advantageous indeed. If it were so used would not the plaintiff at once say, "That is within my patent?" There would be no defence to such a case. He would point out that he confined his invention to all electrical consuming appliances—that Fig. 5 was only an illustration of its use with one such appliance. Indeed, heaters and cookers might take the place of motors. Such were known in 1882. There is no limit to the purposes for which electricity may not be used—lifts, &c. Can it be said that because it is most useful in one system of electric lighting that, *ergo*, it is confined to that system—the parallel system? The comic part of this argument is that my friends are taking pains to show it is not useful for a particular purpose, while we show it is. If arc lighting be held to be included, what is the result to plaintiff's case? The reply is too obvious to mention. They cannot show its want of utility in order to narrow its meaning. Now to consider the claim. With "electrical distribution or supply" I have already dealt. The plaintiff's counsel now read the rest of the claim in a forced and erroneous manner. It may be convenient for the patentee to attempt to narrow its meaning now, but the narrow construction is not one that can be fairly put, nor which the patentee would put himself were he wishing to restrain other infringers. Now as to the rest of our case. I shall prove that in the winter of 1880-1 Mr. Crompton's firm had instructions to light the Alexandra Palace. Wishing to economise copper, they proposed to use two dynamos for two arc lights with a common return conductor. They found on working their arrangement that one dynamo "reversed" the other, so that they became in series instead of in parallel. Mr. Crompton then let them so act, and they worked very well. It was so worked for some months and then taken down. There were only two arc lamps. This invention was in that way hit upon by accident; it worked exceedingly well and gave considerable advantages in the way of economy. In the Inchicore anticipation a single dynamo with two coils on a single armature is used. This the patentee admits to be the same thing as two dynamos. [Mr. ASTON: Could *be made* the same thing.] It is the same as two dynamos coupled in series by rigid connection which is necessary in the case of an alternating dynamo. This machine was put up at Inchicore in March, 1882. It has been at work ever since and is used for arc lights in parallel. This case would clearly be an anticipation, if my construction of the specification is the correct one.

Hosted by Google

In the particulars of objection we state that other similar machines were made and sold by Messrs. Siemens. One instance we will prove where the machine was used on board s.s. "City of Berlin." Within the last few days we have received intimation of another case of anticipation. The National Electric Lighting Company of Glasgow's Manager, Mr. J. Andrews, was duly furnished by Messrs. Siemens with a machine of the same character as the Inchicore one. The Company altered it in their own works, and instead of using it with arc lamps in series they used it in parallel with incandescent lamps. This is the anticipation already mentioned to the Court in connection with the amendment of the particulars of objection. It was so used for about 11 months before March, 1882. The Company not being very successful, was wound-up; the user of their machine was open to members of the public. We submit that if we prove Alexandra Palace and Inchicore cases we have proved enough. The new anticipation, if we go into it, covers the whole ground. But suppose that our construction of the specification is wrong and that my friends are right in saying that it is to be confined to incandescent lighting in parallel, then the question arises, Is that invention subject-matter for a patent? The plaintiff may have made a very useful discovery with regard to the advantages of its use with the parallel bridge, but not every discovery is a patentable invention. In the recent case of *Lane Fox* v. *The Kensington and Knightsbridge Company*, Lord Justice Kay in the Court of Appeal used the same argument, and pointed out that Mr. Lane Fox merely told people how to use one well-known thing in connection with another well-known thing. Here the three-wire system was well known. It was used with arc lamps. The parallel system was well known also, and the plaintiff only proposed to use these well-known things without change in connection with each other. We have the three-wire system known, know also how to change from arcs in series to incandescent lights in parallel—no change required in the three-wire system. We merely exercise our right of substituting incandescent lights in parallel for arcs in series. Then Dr. Hopkinson points out we shall gain a certain advantage. Is that invention? Is that subject-matter? He has nothing to tell us as to changing the three-wire system. I will *suppose* that Dr. Hopkinson knew (what we believe he did not know) that the three-wire system had been employed at Inchicore and the Alexandra Palace, and suppose, consequently, he said in his specification, "I am aware that the three-wire system has been used in such and such cases. Now, my invention consists," &c. Could any one suggest that it would be subject matter? Hence if the narrower construction be the correct one we say there was nothing left for Dr. Hopkinson to invent, and that his invention is not subject matter. On the other part of the case, as I have the book here, I may refer to *Harwood* v. *Great Northern Railway* (11, House of Lords cases, page 681), it is laid down that the proper test in such a case is to consider whether the anticipation set up would have been an infringement had it been done subsequently and not prior to the plaintiff's patent. There can be no doubt but that it would be an infringement for anyone to apply his system to arc lights or electro-motors. There remains one other matter. We also say that in addition to the points already mentioned the patent is void, on the grounds of (1) want of utility and (2) insufficiency of specification. I refer to the application of the invention with regard to alternating currents. The specification reads :—"The foregoing description of instruments relates more particularly to continuous currents, but it is obvious that the arrangements (Figs. 1, 2, and 5) are also applicable to alternate currents; but in that case the iron in the electro-magnetic apparatus must be so divided that local-induced currents are prevented." Now, if the patentee says in his specification that his invention is useful in cases A and B, and it fails in B, the patent is bad. The cases of *Reg. v. Cutter* and *Simpson* v. *Holliday* are in point. Foucault currents can be got rid of by dividing the core; I do not refer to them, but speak of the induced currents arising from the magnetic core, wound as the patentee describes, acting as a "transformer," and inducing currents in the adjacent wires. The existence of such currents is not denied by any of the scientific witnesses. Dr. Hopkinson and Lord Kelvin said it would not affect the working of the apparatus. Sir F. Bramwell said that these currents would be allowed for in adjusting the wires. Neither of those witnesses nor Mr. Belfield had ever tried it; they had no actual experience, their evidence is merely theory and opinion based on general experience and knowledge. Mr. Belfield said it had been used with additions. Our people have examined it. Mr. Belfield told us these additions had nothing to do with the removal of induced currents. He said that when one had a very high pressure, and reduced it by well-known means to a pressure which was practically safe to use, such an operation had nothing to do with these induced currents. My witnesses were surprised at that evidence. They think that these induced currents would have such an effect on the current as to interfere with the working of the system—that is their opinion. But we have seen their instrument. We found it was not used, and is now discarded. They use some other means. So it turns out that the instance proved is no instance of successful use at all. We know now it will not work. Why that is is not the question. If it is of such great value as one would conclude from the model, is it not most extraordinary that no one should think it worth while to employ it? If they say, as they are entitled to, it will work with a modification, then I say that amounts to insufficieney of specification. The patentee has omitted to give certain directions which will make it work with alternating currents. The same point arises in the application of the three-wire system to alternating currents. It is difficult to get two alternating dynamos to work together; a slight difference of speed would put them out; they must be absolutely in unison. In practice this difficulty is met with by using one dynamo having two coils on the one armature instead of two dynamos. Instead of the two coils on one armature the two dynamos may be coupled by a rigid connection, as, for instance, using a common axis. But the specification contains no directions as to the overcoming of this difficulty. The plaintiff meets this objection in an ingenious manner. He says that in 1882 it was not known that alternating dynamos in series could be coupled otherwise than rigidly, that it was a subsequent discovery. But Wilde told the public that in 1869, hence it was common knowledge in 1882, and express directions were necessary for rigid connection. As the patentee has described a machine to work with both kinds of couplings which will work with one only his patent is bad. The only answer the patentee attempts to make is that in spite of Wilde's publication the electrical workman would only know of rigid connection for alternating dynamos in series. I have endeavoured to lay before the Court the outline of our case. Our scientific witnesses will correct any inaccuracies in the mode of expression.

Mr. WILLIAM LEWIS CRESSWELL was then called and examined by Mr. FINLAY. Witness stated that he was foreman of the Hydraulic and Electric Lighting department at the Great South Western Railway Company's Station at Inchicore. He remembered a machine coming from Messrs. Siemens in March, 1882. The machine had remained in the same condition, and had been used in the same way ever since.

Mr. EDWARD LAUCKERT, called and examined by Mr. FINLAY, stated that he had been the works manager of Messrs. Siemens Bros.' electric lighting department since the beginning of 1880, and it was under his directions that the machine supplied to the Great South Western Railway at Inchicore was wound. There were ten bobbins, all wound in the same direction. The whole machine was connected in series. In the centre of it a wire was taken to a return, so that the machine was connected on the three-wire system. It had three collector rings. The diagram J. H., 8, represented the working of the machine. In a machine so wound the third wire only conveyed the difference in current between the two circuits, but if only one circuit was burning then it conveyed the whole current of that circuit. He had given directions for winding another similar machine which was supplied to the National Electric Company of Glasgow. He gave the directions for winding that machine on January 18, 1882, and for the first one on January 4, 1882. The Inchicore dynamo was sent away on January 24th, and the Glasgow machine was sent away from Woolwich on March 1st. He estimated that by working the Inchicore dynamo, which gave a total useful work of about 3,960 watts, on the third-wire system there was a clear saving of 414 watts.

Cross-examined by Mr. MOULTON, witness stated that he did not go to Inchicore. All that he had to do with was the making of the machine and directing them to put it up. What he meant by the watts gained was that if he had to work two sets of five-lamps in the ordinary way he would have four wires, whilst in this way of working he need only have three wires.

Mr. JOHN NEBEL, examined by Mr. ROGER WALLACE, stated that he had been in the employ of Messrs. Siemens Brothers since 1874. He agreed with the evidence given by Mr. Lauckert.

Cross-examined by Mr. ASHTON, witness stated that he did not know that Messrs. Siemens in Germany were licensees under Dr. Hopkinson's patent. He could not say whether an application was made by Dr. Siemens to patent the third-wire system in this country.

Mr. WILLIAM SCHARINA, examined by Mr. FINLAY, stated that he had been in the employment of Messrs. Siemens for a good many years. He was employed by them to see to the starting of the machine at Inchicore. It was set up as per diagram J. H. 8.

Mr. THOMAS BONSALL CROMPTON NUTTALL, examined by Mr. ROGER WALLACE, stated he took the measurements on which the calculation was based by Mr. Lauckert.

Mr. EDWARD LAUCKERT recalled, and further cross-examined by Mr. MOULTON, said that his calculation would have been substantially the same if whenever he turned the ten lamps on he broke connection with the third wire.

Mr. WILLIAM HENRY ILLINGSWORTH, examined by Mr. FINLAY, stated that in the year 1880 he was in the employment of Messrs. Crompton and Co. The installation at the Alexandra Palace was used in the summer time in lighting the grounds and after that for lighting the Palace itself during the winter. The plant consisted of H. A. wound dynamos, a Marshall's portable engine, and Crompton arc lamps, series wound. The output of the dynamos was about 50 volts and a little more than 20 amperes. He was in charge of the plant. The dynamos were arranged to run two in parallel with a common return. According to J. H. 7, they were using two insulated conductors and a bare copper wire in the centre. On starting he found at once that one of the machines had reversed, so that the machines were running in series. He continued to run them in that way for the whole time that they were lighting the central hall. This would be December, 1880, and January, 1881. There were only two arc lamps in the circuit in question. The size of the insulated wires was 7/16, their length was something like 315 yards, and the common return was No. 8 bare copper wire.

The Court then adjourned until Monday.

MONDAY, NOVEMBER 7TH.

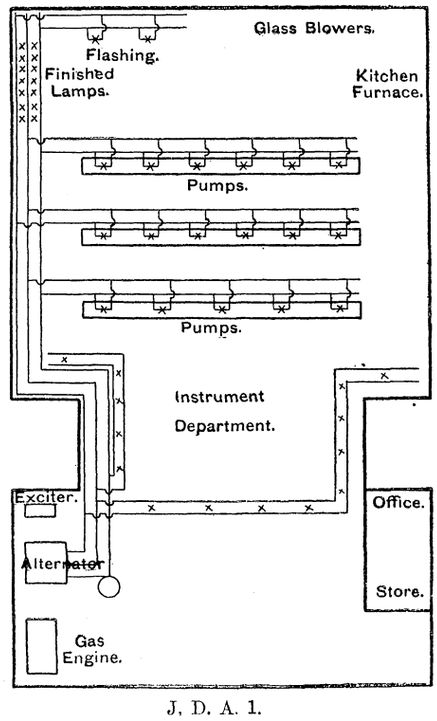
On the resumption of the hearing of this action, Mr. ROOKES EVELYN BELL CROMPTON was called, and examined by Sir HORACE DAVEY. Witness stated that he put up an installation for the purpose of lighting the Alexandra Palace in 1880 largely with his own hands. In those days they were all working themselves. [Witness then minutely described this installation.] The type of lamp used had the trade name of "E." It was the latest type of lamp he made previous to the use of differential coils. These lamps would not burn at all on an ordinary two-wire circuit in series. They invariably went out each time the lamp had to be fed. They worked quite satisfactorily with the three-wire arrangement. The third wire enabled the difference of the currents of two lamps to be dealt with by the dynamos exactly in the same way that the difference between currents on the two parts of the three-wire system were now dealt with by the dynamos. There was a current passing either one way or the other up or down the third wire. He had the actual advantage of using three wires instead of four, and he could have reduced the size of his leads. In the year 1880 it was not unknown to use arc lamps in parallel.

Hosted by Google

Cross-examined by Mr. MOULTON, witness stated that leaving out Andre and Werdermann, he knew of no public user of lamps in parallel in England before July, 1882. Witness was perfectly confident his lamps were not provided with a shunt coil for regulating. His firm had erected 2,000 odd incandescent lamps by the time Dr. Hopkinson's provisional patent was taken out, and nearly half of those were in one large installation at the Birmingham Town Hall on a five-wire system. The wires did not come back to the dynamo. On the occasion of the reading of a Paper by Mr. Preece at the Society of Arts, on March 7, 1884, he did not remember Mr. Preece saying, "A marvellous improvement has been made by Dr. John Hopkinson and by Mr. Edison, independently of each other, by which the weight of copper necessary for central station working has been diminished 60 per cent., and this is due to the use of two dynamos connected in series, and a third or compensating conductor placed between them as shown in the accompanying diagram, *see* next page." He spoke on that occasion, but did not remember saying anything about that not being an invention or his having discovered it two years before. He had mentioned to Dr. Hopkinson himself that he had done something of the kind at the Alexandra Palace, which witness thought would invalidate his patent. Probably in 1883. He did not remember saying anything at the discussion at the Institution of Civil Engineers in November, 1884, on a Paper by Prof. Andrew Jamieson, to the effect that he had anticipated Dr. Hopkinson. He never accepted Dr. Hopkinson's patent as a satisfactory solution of the difficulty.

Mr. JOHN SMITH RAYWORTH, examined by Mr. FINLAY, stated that while acting as agent for Messrs. Siemens at Manchester he fitted up the steamship "City of Berlin" with electric lighting apparatus. This was in November, 1879. The machine was a Siemens alternator, and it had a separate exciter. It was wound in two circuits in series, with three collecting rings. It was the same sort of arrangement as the Inchicore arrangement. Siemens' differential arc lamps were used. There were eight; four on two circuits. The third wire acted in the first instance simply as a divider of the two circuits, so that they were able either to burn the steerage lamps or the saloon lamps, or both, as desired. Then it acted as a protector of one circuit from the inequalities of the other. Reading the specification by the light of the knowledge he possessed in 1882, the reference there made to alternators would not have conveyed to his mind the idea that the two dynamos had to be rigidly coupled together.

Mr. JOSEPH DAVENPORT ANDREWS, examined by Mr. FINLAY, stated that he was formerly in the employment of Messrs. Siemens. He subsequently went to the National Electrical Company in Glasgow, and ordered an alternator wound in the way described. It was used with incandescent lamps, partly for lighting the workshop and partly for manufacturing purposes of incandescent lamps; the machine was bought for the purpose of manufacturing incandescent lamps. The connections were as in the diagram marked J. D. A. 1.



J. D. A. 1.

Mr. ASTON: I have followed this with great care, as your lordship will imagine, and I am justified in saying that the evidence does take us by surprise, for we did not expect it.

Mr. JUSTICE ROMER: I will accede to your application. Are you going to apply for an adjournment?

Mr. ASTON: My application is that we should adjourn to consider what our position is.

After some little discussion the Court adjourned, subject to any application in the meantime, with notice on either side, until Monday next, the 14th inst.

Pepperill v. The City and South London Railway Company.

On Thursday last week, in this action, the plaintiff appealed to the Master of the Rolls and Lords Justices Lopes and Kay from a judgment of Mr. Justice Wills, who heard the case in May last. The cause for action, and other particulars, will be found in *The Electrician* of May 27th, p. 102. The Master of the Rolls upheld Justice Wills's judgment, and dismissed the appeal.

Donovan v. Laing, Wharton, and Down.

This was an action before Mr. Baron Pollock and a special jury to recover damages for personal injuries caused by the alleged negligence of the defendants' servants. The defendants denied the alleged negligence, and asserted that there had been contributory negligence on plaintiff's part. Mr. Cock, Q.C., and Mr. Lynden Bell appeared for the plaintiff; and Mr. Lawson Walton, Q.C., and Mr. Rawlinson for the defendant. The jury returned a verdict for the plaintiff for £500 damages; but judgment was not entered, as points of law in regard to defendants' liability have to be argued.

Re the International Electrical Syndicate (Limited).

In the Queen's Bench Division, on Wednesday last, a petition for the winding up of the above Syndicate came before Mr. Justice Vaughan Williams.

Mr. FILLAN said he understood the petition was unopposed. The nominal capital of the Company was £12,000, and the amount paid up was £10,000. The application was by a shareholder, who had a holding of £500 paid up. The object of the formation of the Company was to buy some patents for electrical motors, and to work them in England. The Company was incorporated in April, 1891, and since then nothing had been done. He therefore applied under the 79th Section of the Act for a winding up. The registered office of the Company had been closed altogether; in fact, it had never been opened at all.

The order for winding up was granted.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October* 28, 1892.

The American Street Railway Association.—The eleventh annual convention of the American Street Railway Association, which was held in Cleveland, Ohio, on October 19th, 20th and 21st, was the largest, and in some respects the most important of any in the history of the Association. The attendance reached nearly 600. A number of important Papers were presented by various street railway men and discussed at considerable length. It was noticeable that a large proportion of the Papers were upon electric roads. While the Papers themselves contained matter of importance, it is to be regretted that the discussions were not more general and more complete, as this is often the most valuable feature of such a meeting. The exhibition of street railway apparatus was the largest and most interesting collection that has ever been brought together in this country. The display of the General Electric Company surpassed all former ones of the Edison or Thomson-Houston Companies, and the Short Electric Railway Company, and the Westinghouse Company also made very elaborate exhibits, while a large number of other firms were represented to a greater or less extent. The formation of a Supply Dealers' Association in connection with the American Street Railway Association was considered, but the Executive Committee decided that there was no necessity for such an Association at the present time. The supply dealers themselves, however, were not satisfied with this decision, and held a special meeting at which a Committee was appointed to confer further on the subject with the Executive Committee of the Street Railway Association.

The New Westinghouse Lamp.—At the time of the decision of the United States Circuit Courts of Appeals in favour of the Edison General Electric Company the Westinghouse Company announced that it was prepared to place upon the market a new form of incandescent lamp which did not infringe in any way upon the Edison patent. At that time no definite information could be obtained in regard to the construction of this lamp, but now the matter has been made public, although the lamp itself has not made its appearance. The lamp is of the keyless type, and the base is of glass instead of brass. No platinum is used for the leading-in wires, its place being taken by an alloy, which is claimed to be a satisfactory substitute and to

Hosted by Google

have a proper coefficient of expansion. The lamp is a separable one, that is, the filament can be removed and the bulb used over again. This is accomplished by attaching the burner to the ground-glass stopper, which is duly inserted in the bulb, and the air is then exhausted. The lamp is sealed by a base, and when it is necessary to remove the filament the lamp is placed in hot water, which softens this sealing compound and permits the removal of the stopper, which, when refitted with a new filament, can be replaced and again exhausted. The connection with the socket is made directly through the leading-in wires, the base is of porcelain, of very simple construction. The binding posts are connected to two spring clips, with which contact is made by turning the lamps so that the wires are at right angles with these clips, which are thus forced apart, one wire pressing against each. A quarter turn of the lamp places the wires parallel and between the clips, which then spring back to their normal position, and the light is thus extinguished. The shell of the socket is nickel-plated, and the lamp is simply pushed into it, it being retained by the springs on the side. It is claimed that these lamps can be sold as low as 30 cents each.

CORRESPONDENCE.

SUNSPOTS AND MAGNETIC STORMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: M. Ricco's investigation of the time relation between sunspots and magnetic storms is very interesting. It is rather unscientific to assume a new ether to explain every new phenomenon, and there are very serious difficulties in the way of believing that the very long ether waves, thousands of miles long, which would act on the magnetometers used in magnetic observatories, could be emitted as a beam from the sun and not be spread over a very large angle by diffraction long before they reached the earth. Except for this there does not seem any great difficulty in assuming that the beam is not emitted perpendicularly to the solar surface. If it came up the sunspot like a beam out of a lighthouse all that need be assumed is that the line of the sunspot is not perpendicular to the solar surface, and that it points backwards as regards the solar rotation, a not impossible assumption. However, the difficulties of diffraction already mentioned make it very improbable that it is a direct action of an electro-magnetic wave started by the sunspot. It is just possible that, as Prof. Perry suggests to me, a very rapidly vibrating electro-magnetic beam, so rapidly vibrating that its short waves would not spread much by diffraction, could unsettle the magnetic equilibrium of the earth, in the same sort of way that striking a match may light a fire, or a burning glass light paper; but there does not seem much evidence that the magnetic equilibrium of the earth can be so upset.

What seems a better hypothesis is that a sunspot is a source from which some emanation like a comet's tail is projected from the sun. It is known that comets' tail are explicable on the hypothesis that the sun is powerfully electrified, and repels similarly electrified molecules with a force of some moderate number of times the gravitation of the molecules to the sun. With intense chemical actions taking place in the sun, it seems not improbable that chemical atoms highly charged may be produced and repelled like comets' tails from the solar surface. In fact, several of the phenomena of the corona have long been attributed to such a condition. Is it possible, then, that matter starting from the sun with the explosive velocities we know possible there, and subject to an acceleration of several times solar gravitation, could reach the earth in a couple of days? In the first place, it is to be remarked that inasmuch as this action hits the earth, even though the sunspot is not apparently in the plane of the ecliptic, it must diverge in a cone of 15deg. or 20deg. aperture from the spot, and that the forward edge of the cone would reach the earth when the sunspot was 20deg. from the central meridian, only for the delay M. Ricco attributes to the time taken to reach the earth. This consideration increases the delay to about four days, and reduces the average velocity to about 300 miles per second, which does not seem at all excessive. Now, as to the quantity of matter that need exist in this cometary beam, in order to act as an electric current on the earth. We may assume each atom to have the usual atomic charge, and it appears from an obvious calculation Dr. Lodge and I worked out in the train the other day, that a few cubic metres of hydrogen at atmospheric pressure and temperature spread over a volume a thousand miles cube would represent a current of some thousands of amperes, which seems amply sufficient to disturb magnetometers very seriously. Considering the connection between sunspots, magnetic storms, and some coronal phenomena, this comets' tails hypothesis seems much more probable than a direct electro-magnetic wave propagation.—Yours, &c.,

GEO. FRAS. FITZGERALD.

Trinity College, Dublin, November 7, 1892.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The Institution of Electrical Engineers is the principal corporate representative of an important and increasing profession; in its early days, and especially when it existed as the Society of Telegraph Engineers, it was the principal exponent of the scientific aspect of electrical progress, and attracted a large number of gentlemen only indirectly connected with practical engineering. Under those conditions it was appropriate that the Council should have been composed to some considerable extent of professors and similar representatives of purely scientific effort. The Council, which has the responsibility of nominating its own members, has always given due, if not excessive, prominence to this idea, with the result that at the present time, notwithstanding that the membership now includes a very large number (in fact a considerable majority) of electrical engineers actually engaged on important works, that body consists of:—10 actual or nominal professors; 4 physicists; 11 present or past representatives of Government departments, including naval and military officers; 7 electricians and electrical engineers, in all 32; or omitting the vice and past presidents it consists of: 5 actual or nominal professors; 7 present or past representatives of Government Departments, including naval and military officers; 3 electricians and electrical engineers, in all 15.

From a consideration of the above list, which the most vivid imagination would have difficulty in recognising as representative of the present membership of the Institution of Electrical Engineers, we turn with relief to the Institution of *Civil* Engineers, an association which has earned the respect not only of this but of all civilised countries, and whose principles and procedure may with advantage be imitated by other societies aiming at similar objects. Their Council is composed almost exclusively of engineers in actual practice, it contains only six representatives of Government Departments and no professors. It must not be considered from the above remarks that any professor who sits on the Council of the Institution of Electrical Engineers is not in every respect an ornament to that Council, and that his presence there does not give satisfaction to the whole body of members and associates, for we fully believe that the contrary is the fact. In approaching this question we wish to deal exclusively with numbers, and we have neither intention nor desire to approach the subject from the point of view of the personal or contingent qualifications of individuals, for notwithstanding that we, in company with other members, entertain a high personal regard for each and every member of Council, we feel that it is imperative in the interest of the Institution that that body should be truly representative, no class or interest predominating over others.

We have accidentally commenced with the professorial element, but there can be no doubt also that the various departments of Her Majesty's Government have at the present time a representation much in excess of their share in general electrical work, and that some of the seats held by both the above-mentioned classes might with advantage be distributed amongst other branches of the profession.

We know that our views as expressed above are shared by a large and influential section of the Institution, and we believe

Hosted by Google

also by some members of Council, who would have given effect to them had they been supported by any general expression of opinion. We do not advocate, as politic or possible, the making of any immediate radical change in the constitution of the Council; but we do advocate a gradual modification of it, by the nomination on the part of the Council of new members, actively employed in constructive work to replace others retiring in rotation, until a more equal balance be attained. As the date of the annual election is approaching we have taken the liberty of bringing this subject forward through the medium of the Press, in order that an opportunity may be afforded to members of the Institution of expressing their opinion on a subject which we are assured is attracting serious and increasing attention.—Yours, &c.,

R. S. Erskine,
E. Manville,
London, November 7, 1892. Alfred E. Mavor,
John Raworth,
A. A. C. Swinton.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Tenders Invited.—The Corporation of Blackpool invite tenders for the installation of wires, switches, &c., for the electric lighting of the new police-station buildings. Plans, specifications, and forms of tender may be obtained from Mr. J. Wolstenholme, borough engineer, by whom tenders must be received not later than the 25th inst. Further particulars appear in our advertisement columns.

——— The Bristol Urban Sanitary Authority require tenders for the supply, delivery and erection of underground feeders, mains, arc light circuits, junction and house boxes, arc lamps, posts, and suspension gear. Some particulars will be found elsewhere, but full particulars can be obtained of Mr. D. Travers Burgess, town clerk, 51, Prince-street, Bristol, and tenders must be in by Thursday, December 1st.

——— The Asylums Committee of the London County Council require for the installation of the electric light at the London County Lunatic Asylum at Claybury (Woodford), Essex. Further particulars are given in our advertising columns, and full information can be obtained of the Clerk to the Committee, 21, Whitehall Place, S.W., after Monday next. Tenders must be in not later than noon on December 6th.

——— The Controller of Stores of the General Post Office invites tenders for the purchase of various stores, including india-rubber, gutta-percha, and old metal. Forms of tender may be obtained from the Controller, Telegraph-street, E.C., and tenders must be in by noon on Tuesday next, the 15th inst.

——— The Corporation of Derby invite tenders for the builders' work in the engine and boiler-house, &c., and accessories, at the central station. Tenders to be in by Monday next, the 14th inst.

——— The Director of Army Contracts invites tenders for the purchase of about 460 tons of old metal of various kinds, including copper, nickel, brass, &c. Particulars can be obtained of the Director-General of Ordnance Factories, Royal Arsenal, Woolwich, and tenders have to be in at the War Office, Pall Mall, S.W., by Friday, the 18th inst.

Sale by Auction.—Messrs. Wheatley Kirk, Price and Goulty announce in our advertisement columns that they are instructed to sell by public auction, at an early date, the entire contents of the works of Messrs. A. B. Gill and Co. at Gilmore-road, Lee, comprising electrical and engineering plant, tools, stock, fittings, stores, &c.

Dissolutions of Partnership.—Messrs. J. H. Geisenheimer and E. A. Lessing, carrying on business as electrical engineers at 10, Glasshouse street, London, W., under the title of Watson, Geisenheimer and Co., have dissolved partnership, and the business will be carried on in future by Mr. E. A. Lessing, who will pay and receive all moneys owing by and due to the late firm.

——— In reference to the Trade Note appearing in our last issue we are asked by Mr. Roger Dawson, of the late firm of Rashleigh Phipps and Dawson, to state that he has purchased Mr. Rashleigh Phipps's share in the business as from October 14th last, and that the business will be carried on at 53, Berners-street, as hitherto, under the style of Roger Dawson, as will also the works at Stanhope-street, N.W., and the branch establishment at Bournemouth. Mr. Roger Dawson will receive and discharge all debts due to and from the old firm.

Removal Notice.—The Phonopore Company (Limited) has definitely removed its offices from Bloomfield House, E.C., to Faraday House, Charing Cross, W.C.

Patents, Designs, and Trade Marks' Acts.—Notice is given in our advertising columns that Signor Michelangelo Cattori, of Rome, has applied for leave to further amend his letters patent, No. 14,234 of 1891, for improvements in, and relating to electric railways.

Blackpool Electric Tramway Company (Limited).—At extraordinary general meetings, held on September 24th and October 15th, a special resolution was passed and confirmed that the Company be voluntarily wound up, and that Mr. John Oddie, of Halifax, be the liquidator.

Collier Audible Telephone Syndicate (Limited).—At extraordinary general meetings, held on October 1st and 17th, a special resolution was passed and confirmed that this Syndicate be voluntarily wound up, that Mr. Godefroi Drew Ingall be the liquidator, and that the liquidator be authorised to carry out the sale of the assets on the terms of the contracts made between the Syndicate, Mr. E. Hampson, and the Collier-Marr Telephone and Electrical Manufacturing Company (Limited).

Froude-Hurrell Torpedo Company, Limited (in Liquidation).—Notice is given in the *London Gazette* that Messrs. H. Jasper, W. Mackie, and H. C. Knight have been appointed a committee of inspection to act with the official receiver and liquidator.

Electrical Assets Purchase Company (Limited).—A meeting is to be held at Mr. W. R. T. Carr's, Monument House, Monument-yard, E.C., on the 28th inst., at 2 p.m., to receive the report of the winding-up.

Failure.—The failure is announced of Mr. Thomas Griffiths, managing director of Griffiths Pyrodene Fireproof Company (Limited), with gross liabilities of £17,148, of which £12,998 are expected to rank, and assets estimated at £2,605.

Ship Lighting.—Messrs. G. E. Bellis and Co. have recently supplied the electric lighting engines and accessories for the two new Cunard liners, the "Compania" and "Leuconia."

Messrs. Russell and Co.—As notified in our issue of the 28th ult., this firm have commenced business in London as electrical engineers and contractors. They propose to list and supply requisites for electrical work of all descriptions, and to contract for the supply, erection or equipment of any desired plant. A complete catalogue is in preparation.

Electrical Supplies and Fittings Company (Limited).—This Company are busy with the wiring and fitting of a number of West-end houses and business establishments, including an extension of the lighting in the school-room of St. Jude's Church, Kensington.

Messrs. King, Mendham and Co.—This firm send us a large illustrated sheet of electrical accessories manufactured by them. The sheet will be handy for reference, and is provided with tabs for hanging in the office or laboratory. In the centre of the sheet, on both sides, is some useful information.

Messrs. Crompton and Co. (Limited).—Extensive new plant has recently been laid down at this Company's works at Chelmsford, including a 240-H.P. boiler, supplied by Messrs. Penman and Co., of Glasgow. The new engines are by Messrs. Willans and Robinson (Limited).

Crompton-Howell Accumulators.—The Crompton-Howell Company have, we learn, recently secured an extensive order to supply accumulators to the New York Central Lighting Station.

The Oerlikon Machinenfabrik.—We have received from this well-known firm a well-illustrated and interesting pamphlet relating to their electric traction apparatus. Several views are given of electric lines laid down by the Oerlikon engineers, the lines, with the exception of that at Marseilles, running up mountains. The motors are of the multipolar, single-reduction type, with ring armatures, carrying conductors in deep slots.

United Electric Wire Company.—This Company issue a second edition of their price list of wires and cables. They call particular attention to some useful tables on pp. 4, 5, and 23, the latter of which is a Wire Price List and Ready Reckoner.

Messrs. J. H. Pickup and Co. (Limited).—We have received a catalogue from this firm giving particulars of the Pickup Electrical Fan, the Pickup Dynamo, and the Britannia Air Propeller. The list is fully illustrated.

Messrs. D. and G. Graham.—This firm have secured the contract for the electric lighting of the Central Hotel, Belfast. The installation is to consist of 576 16 c.p. lamps and several arcs; the two dynamos to be supplied have each to be capable of maintaining the whole number of lights.

Hosted by Google

CHRISTMAS AND THE NEW YEAR.—Those of our readers who contemplate despatching letters, books, or parcels, abroad for Christmas and the New Year, will find the postal arrangements set out in a circular, No. 49, recently issued by the Post Office.

ASHFORD.—At the last meeting of the Local Board a communication from an electric lighting company, proffering to supply information in relation to the question of the public lighting of Ashford was referred to the Lighting Committee.

BANDON.—It is stated that a company will shortly be formulated with a view to provide the electric light for the town of Bandon.

BELFAST.—The concluding article (No. 22) on Electric Lighting, by the *Belfast Evening Telegraph's* Special Commissioner, appeared in the issue of that Journal for November 4th. The result of this series of articles has, we understand, been gratifying to the proprietors of that Journal, who are to be complimented upon the energy displayed in providing information on the subject of electric lighting generally at a time when the matter was occupying the attention of the Belfast public.——Mr. J. H. Greenhill delivered an interesting lecture on the practical application of electricity, on Wednesday last week, to the members of the Natural History and Philosophical Society. The lecturer brought to his aid a quantity of electrical apparatus—lamps, &c.—to illustrate his remarks. An interesting discussion followed the lecture, which was listened to with attention by a large audience. Probably in no town in the kingdom is the subject of electric lighting more keenly discussed than in Belfast, and Mr. Greenhill received an enthusiastic vote of thanks for his lecture at its termination.

CARNARVON.—An agitation is on foot in Carnarvon for the introduction of the electric light, serious complaints being made against the gas service. The price of gas is 4s. 6d. per thousand, and it is stated to be of most indifferent quality. The gas is under the control of the Corporation.

CHISWICK.—The special Electric Lighting Committee of this Board have met, and have recommended that body to take over the transfer of the Board of Trade Order.

DUBLIN.—Messrs. Curtis Bros., of Suffolk-street, Dublin, have several important installations in hand, amongst them being the providing of a handsome wrought-iron crescent out-door electric illumination for the Sun Insurance Office. This takes the form of a wrought-iron crescent over the entrance, in the centre of which is arranged a large sun, with six lights. This novelty is to be provided with an automatic cut-out, so that the light can be extinguished at any hour of the night automatically. The device is made from suggestions by the Sun Company's engineer.

DUNDEE.—At a meeting of the Dundee Chamber of Commerce on Friday last, on the appointment of the Gas Commissioners, a discussion arose on the electric lighting scheme which had been adopted. It was announced that the whole of the arrangement for lighting the central area had been completed. It was further announced that applications for 1,000 lights of 16 c.p. had been received, being about a fifth part of what they would be able ultimately to supply.

EALING.—The Electric Lighting Committee of the Local Board have presented a report, in which they recommend that "five or six electrical engineering firms" be invited to send in schemes for lighting the Uxbridge-road, from the boundary of Hanwell to the Ealing Common Station, and through the southern part of the district, from the Broadway to South Ealing Station. A discussion ensued as to the desirability of the Board's consulting an expert prior to inviting the firms referred to to send in their schemes, and the report was ultimately referred back to the Committee for reconsideration on this basis.

EAST MOLESEY.—At the last meeting of the Local Board a fresh plan for the lighting of the district by electricity had been submitted, and a Special Committee was appointed to consider the subject.

LEICESTER.—A series of free lectures is being held in the Art Gallery of the Leicester Museum, and the third of the series was given last Thursday by Mr E. E. Brooks, the subject being, "Forms of Electrical Discharge." The room was well filled, and the lecturer received a hearty vote of thanks at the conclusion.

LIVERPOOL.—The *Liverpool Daily Courier* of Monday last contained an interesting account of the Victoria Building, Liverpool University College. The electric light fittings and metal work have been supplied by Messrs. Hart, Son, Peard and Co., the general lighting arrangements having been conducted under the superintendence of Mr. A. L. Taylor.

MERTHYR.—It has been decided by the Board of Health to defer the consideration of the question of the electric lighting of the town for 12 months, in order that the Lighting Committee may visit various towns for the purpose of obtaining information.

PONTYPOOL.—In connection with the Pontypool Electric Light and Power Company a luncheon was given on Wednesday in last week to celebrate its formation. Mr. J. C. Howell was able to announce that support had been promised for the new venture to the extent of 1,200 lights.

WOKINGHAM.—A proposal having been made that the Town Council should purchase the Gas Works, it was proposed at the last meeting of the Council by Alderman Moorcock that they should apply for an Electric Lighting Order. A resolution was passed that a committee of five members be appointed to consider the general question of lighitng the town.

YARMOUTH.—A report has been received by the Yarmouth Town Council from Mr. W. H. Preece, in which he states that Yarmouth should be able to supply the electric light at 6d. per Board of Trade unit, and thus compete with gas which is 3s. 4d. in that district. In the course of his report Mr. Preece altogether repudiates the notion that the electric light is only a luxury for the rich, and states that, owing to the expiry of patents and other favourable conditions, electrical energy should be obtained by everybody. He recommended the Council to start with an installation of 4,500 lights of 8 candle-power at a cost of about £10,000. In reference to the site for the central station, he strongly recommended that at the north end of the South Denes, where water was abundant and coal was easily delivered. Ultimately, a resolution that the report should be dealt with by a committee consisting of the whole Council (to which Mr. Preece was invited) was agreed to.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

October 14, 1892.

18,399. R. WHITEHEAD and A. DOXEY. Sheffield. Combined telephone switch and ringing key.

18,452. J. GREEN and G. TURNER. Improvements in the manufacture of zinc rods for electrical bells and batteries.

October 15, 1892.

18,465. F. W. GOLBY. London. Improvements in electro-magnetic sounding apparatus. (P. Binsfield and H. von Gleissenberg, Germany.)

18,505. C. CASALONGA. London. Improvements in, or relating to, the supply of electricity to aërial machines.

18,516. E. N. A. PICARD and J. A. TANIÈRE. Improvements in, and relating to, the electro-deposition of metals.

18,520. R. K. BOYLE. London. Improved telephone transmitter and receiver.

October 17, 1892.

18,538. T. WALLACE. London. A new construction of underground conduit for electric conductors.

18,542. J. K. GRINDROD. Manchester. Improvements in certain brackets or supports for electric arc lamps, applicable also for supporting lamps of other kinds.

October 18, 1892.

18,602. S. D. SMITH and O. J. WELLS. London. Improvements in electrical appliances for canes and analagous articles.

18,655. H. SHAW. London. Improved buildings with means of access thereto to supply them with water, gas, also electric light, with electric and steam power, and means to abate smoke.

October 19, 1892.

18,681. S. W. BAYNES. Bradford. Improvements in underground conductors for the distribution of electricity.

18,695. C. A. BANNISTER. London. Bannister's new and improved electric railway, signal and point working system.

18,700. T. S. POOLE and WOODHOUSE AND RAWSON UNITED (LIMITED). London. Improvements in electrical ceiling roses.

COMPANIES' MEETINGS & REPORTS.

Western and Brazilian Telegraph Company (Limited).

The 24th ordinary general meeting of this Company was held at Winchester House, Old Broad-street, yesterday, Mr. W. S. Andrews presiding.

In the absence of the Secretary (Mr. R. M. Cunningham),

The MANAGING DIRECTOR (Major Wood) read the notice convening the meeting and the minutes of the previous meeting, the latter being approved and signed by the Chairman as correct.

The report of the Directors and statement of accounts were, as usual taken as read.

The CHAIRMAN: Gentlemen, as is customary on these occasions, I propose to deal with the receipts in the first case. Of course as we had reason to anticipate so have we reason to realise to-day that, owing to the decreased state of the exchange in Brazil, the outcome of the half-year that we are going to deal with on this occasion will not be found to be so satisfactory as it was on previous occasions. It is quite true that in our case it is not so bad as it has proved to be in many others, because you must have seen from time to time in the newspaper reports of the public meetings of companies that it was shown that owing to this same cause there was no dividend at all. Yet it is far from gratifying for the members of this Board to come before you to-day with a reduced dividend. We have done our best, however, to combat the difficulties that we have had to face, and on the whole, although we regret to see this diminution of gross revenue, we do feel, after all said and done, that it is owing to a cause which we have had no power to control. Well, gentlemen, it is not alone that you have had to deal with a further reduction in the exchange in Brazil; but, as you may remember, there was also a reduction of tariff between this country and Brazil which has had a certain effect in the revenue of the last half-year. The gross revenue for the half-year is £84,021. 16s. 9d., compared with £104,962. 9s. 7d., showing a falling off of £20,940. 12s., no less than £15,539. 14s. 2d. of this owing to the item of exchange. Now, turning to the expenses, these amount to £39,140. 16s. 8d., against £38,638. 10s., showing an increase of £502. 6s. 8d. Now we usually analyse these things, and I will begin by analysing abstract "A." The total under this head is £17,253. 19s. 7d., against £18,765. 6s. 9d., and you see that there is a decrease there of £1,421 7s. 2d. There are, in fact, decreases under ten heads, amounting in all to £2,124. 10s. 8d., and increases under three, amounting in all to £703 3s. 6d., and out of the latter sum no less than £574. 15s. is owing to medical expenses, an unavoidable item on account of the extremely sickly season. You will, therefore, see that there is a very considerable expenditure under abstract "A." Under abstract "B" the result is pleasing in one way, although unsatisfactory in another. It is pleasing in that the ships ought to have shown, and would have shown, a decrease of £2,833 17s. 9d., of which £500, it is true, would have been owing to the "Norseman" having assisted in laying the loops, and to that proportion of her expenses being charged, therefore, to the loops; but there would have been still a reduction of £2,300, but, unfortunately, the "Norseman" was caught in a very heavy gale. She sprung a leak, the sea was extremely high, the vessel was almost—in fact, it was given up for lost. Major Wood reminds me she was really abandoned, that is to say, that the crew had left her, and returned on board the other ship close by. After some time, however, the weather calmed a bit, and she was joined by some of the crew, and was successfully towed to Monte Video, where she was landed in dock. Misfortunes never come singly. Just at this particular period, when that unfortunate vessel was put into dock to undergo repairs, two of our cables took the opportunity of breaking. Well, there was only one thing for us to do. Fortunately, the ship "Scotia," of the Telegraph Maintenance and Construction Co., was on the spot, and we hired her, and by that means we repaired the cables; but, of course, we had to pay the charge, which came to £4,260. At the same time the spending of this money kept the cables going, and prevented the loss of revenue. But for that unavoidable accident—which you will see was again a thing absolutely beyond our control—instead of there being a decrease of £2,832 there would be an increase of £1,487. But you will see again that, in this case as in the former instance, the expenses have been clearly looked after, and we should have had a saving but for that wretched accident. Now, under abstract "C" there is a small increase of £300 under seven heads, and a small reduction under two heads. The outcome of all this is that the receipts amount to £84,021. 16s. 9d., the expenses are £39,140. 16s. 8d., and the balance is £44,881. 0s. 1d. We brought forward for the preceding half-year £4,486. 18s. 2d., so that together these two sums amount to £49,367. 18s. 3d. These are reproductions of the figures in the balance-sheet. We have to deduct interest on debentures, £12,489. 10s. The debenture redemption fund amounts to £6,610. 10s., the reserve is £14,000, the proposed dividend will absorb £14,605. 13s., leaving to carry forward £1,662. 5s. 3d., and make altogether the sum of £49,367. 18s. 3d. Well, gentlemen, of course the enterprisers in Brazil—worked for the benefit of Brazil all round—cannot be very well satisfied with the present inadequate returns which they are getting, and which are most disappointing for the investments made. This is attributable especially to the cause I have named, but also to another. On this occasion, for the first time for a considerable period, we have to deal with a falling off of business. In other words, the times of excitement, which, a year ago, rejoiced our hearts considerably, because they led to the forwarding and receiving of more numerous telegrams, are now ceasing. There is commercial stagnation to a great extent—and so there has been—where there ought to be commercial activity, and, of course, we suffer accordingly. The only consolation is that it seems to be generally felt that an improvement is beginning. We hear from some gentlemen who know a great deal about Brazil and the Plate that that is so, and, therefore, the situation is not altogether so discouraging as the mere figures themselves would seem to point to, because we may hope, after all, that if there is not a good time now, there is at least a better coming. There is another thing which, gentlemen, you have felt the absence of—the sum of £7,000 odd, by way of dividend, which we usually receive from the Platino Telegraph Company, with which we exchange shares. On this occasion that £7,000 is entirely wanting, because that Company suffered very much more severely than we did—under circumstances which are too complicated for explanation—from the losses on exchange, and the consequence was that they could not pay any dividend at all. Then there is a little room for encouragement in the fact that the exchange, which at the corresponding period last year was 11½d., is now at 13d. to 14d. per milreis; and the revenues of the Platino Company up to the present time have, I am pleased to say, owing in the main to this fact, shown a considerable increase. Well, gentlemen, we must hope that that will continue, and that it may eventuate in our getting that money, or some of it, back again. It comes to us, of course, in the shape of a net receipt. It does not cost us anything to earn it. Since our last meeting we completed the last link of those loop cables that we had been laying down for a considerable time. This big operation, I am happy to say, was finished on June 7th, and since that date we have been receiving from the Brazilian Submarine Company that £6,000 per annum, in consideration of which the arrangement was made for laying these loops as predicative of the progress of both companies. The traffic has been kept together, I am happy to say, and although there have been breakages, still, on account of our arrangements for repairs, and one thing and another, they have not materially affected our revenue, and now that the loops are completed the loss will be very small indeed. On the other hand, we have not been able to do all this for nothing. The reserve fund which we possessed has been all invested—I will not say spent—in those loops, and as against a reserve fund producing a certain annual interest, you have an addition which pretty nearly doubles your plant, and entirely doubles it between Pernambuco and Monte Video, which is an earning portion of your line, and which at the same time serves the important purpose of enabling you to work, instead of giving up, one of your broken cables. So your reserve is all spent, and we carry over a small debt-balance of £2,000. I mention that to you because I thought that somebody might have a word to say about the amount that is put to reserve fund. Now you see that we could not help ourselves under the circumstances. The money has been actually spent, and it has been spent in a way of which you, gentlemen, I am pleased to say, have consistently and constantly approved. The Directors stated at the last meeting that if abroad commerce was active, and gave plenty of business, and if the exchange improved, the £50,000 of debentures, which the Company had power to issue, would not be dealt with. Now, circumstances had not been altogether so favourable as that; but, at all events, we had been enabled up to the present to scrape through, and these debentures are consequently still in hand. They have not been dealt with in any way. Of course a great deal depends upon the future. If revenues should be elastic, and we could make more money, then, I think, we could continue to move on and clear off the liabilities which will have to be met for the new ship more particularly, and for other things which have to be done for the security and advancement of your property. At the last meeting, too, we told you that a line had been acquired by a Company called the Central American Company, which was a neutral line at that time between Valparaiso and Buenos Ayres; and that in consequence of the acquirement of that line by the Central American Company it was used for the exclusive purpose of opposing us and taking away the revenue which before we had been enabled to compete for on the West Coast. We reported that in order to get this traffic back again and to repel the attack made on your property we had determined to form a Company to put up a line between Buenos Ayres and Valparaiso, under concessions which had been secured. Well, that project has been so far successful. We did form a Company, the Pacific and European Telegraph Company, and it and the Western and Brazilian Company, and the West Coast Company are all in agreement. The new Company, I am pleased to say, obtained the able assistance of Sir John Pender. The lines are in full course of erection, and will be completed in a few months. When that is accomplished there is no doubt that it will be beneficial to our revenue. I should say with respect to the issue of the debentures that we have been told that if the present improvement should not go on in Brazil and South America, the period for that measure will be within reasonable distance of becoming practicable. We have everything cut and dried, and we are only too axious to go on with it as soon as we are advised to do so by those who know better than we do. The new ship is practically ready to be launched. It is proposed that this should be done on Saturday week. You know the objects for which that vessel has been built—high speed, sufficient carrying capacity, and more economical working. The ship will be under 1,000 tons, whereas the "Norseman" is nearly 1,500, and the cost of the new one will be less than that of the "Norseman." We hope to be able at the next meeting to make a communication to you with respect to these vessels and their arrangements, which will be very satisfactory. As regards our present revenue, it is not unpleasant to remember that it embraces a period during the whole of which two of the opposing lines have been in active competition. Therefore, that shows not merely that we have, I might almost say, surmounted the loss on exchange, but also that entailed on us on account of those two opposing companies which have been actually at work. I cordially wish I could stop there; but all of you must have seen by the newspapers that another—

Hosted by Google

"the cry is still they come"—that another cable has been laid by another competing company between Brazil and French Senegambia. Well, the old opposition with the French Company was more particularly with Brazil, and that with the Central Company was with the River Plate, This new Company is concerned, perhaps, more particularly with Brazil, but at the same time they are competing for the traffic that we get throughout our entire system. What may be the result of that it is impossible to say. We told you long ago that you could not maintain the inflated traffics, because they were quite exceptional. The line was opened on October 5th, so that it is too soon yet to say what may be the result of it. All that we can assure you of is this, that we shall continue to look after your traffic as closely as we have hitherto done. We do not mean to be beaten if we can help it, and we do not mean to lose more traffic than we can avoid. You have enabled the Board by your own sound sense to make a system which those gentlemen, I think, will find it rather difficult to fight with. They have rushed into the fight, it is not our doing. They have attacked us and we are simply defending ourselves. With our duplicated lines, with our experienced staff, and with the duplex apparatus which we have supplied, I may tell you that we have been getting messages from Brazil to London on an average in from 30 to 50 minutes. It will take something to beat that. Well, then, we know that we are accurate, and we think that, generally, we shall hold our own. I do not think, gentlemen, that there is any further observation that I can profitably make, and I do not wish to take up your time by saying anything unprofitable, and therefore I beg to move—

"That the report and accounts for the half-year ended June 30, 1892, be and the same are hereby approved and adopted; and that a dividend for the half-year at the rate of 2 per cent. per annum, free of income-tax, be and is hereby declared, payable on the 11th inst."

I will ask Mr. Coppen to second that.

Mr. JOHN COPPEN: Gentlemen, this being my first appearance on this side of the table, no doubt the Chairman thought it would be more becoming that I should say a few words on this occasion. I have great pleasure in seconding the adoption of this report. I must confess that I would have done it with a great deal more pleasure had we had a more successful half-year; but as the Chairman has explained, and I think very fully, and with the full concurrence of the whole Board, it has been from circumstances over which we had no control. We have had serious difficulties in this Company. It has, indeed, been a very anxious half-year, and the number of questions which have come before us have been of a nature which hitherto had not troubled us. During the six months that I have been on the Board I have learned a great deal of the intricacies connected with telegraphic business, and I can only say that in considering the questions brought before us we have worked in perfect harmony. I have found my colleagues most anxious to give me every information in their power. I have also found in Major Wood a most valuable manager. He has the whole business of the Company at his fingers' ends, and in speaking of Major Wood, I also desire to speak of our friend the secretary. I am quite sure that a more indefatigable officer no Company could possess. As to the opposition that the Chairman has alluded to, I am confident that if we continue to administer the affairs of this Company in the manner in which I have seen them administered during the last six months, and if we carefully watch our expenditure and keep things as low as we can—having always in view efficiency—I have not the least doubt as to the result. Bear in mind that, with a competing company, the first thing that we should take care of is that they do not beat us in the service. We get our messages in the quickest possible time that it can be done in from the Brazils, while at the same time we charge a very moderate price for the service. We are giving to that service our undivided attention, and if it is not sufficient to compete with any ordinary competitor I think that then we shall have to throw up the sponge and say that energy, perseverance, and skill are of little avail against competition. I am much pleased to second the adoption of this report, and I hope that to-day we shall meet with the sympathy of the shareholders rather than with adverse criticism about the circumstances which have brought about this reduced dividend, and which I can only say are circumstances over which we have no control.

Mr. LIDDON wished to point out that there was no allusion to the preferred shareholders, nor any amount recognised as being devoted to the purpose of dividend on those shares. He presumed that it would be paid in the usual way.

The CHAIRMAN said that the whole amount went to the preferred shareholders. He was sorry that there was nothing for the deferred.

Mr. PETO congratulated the Chairman on the clear and straightforward statement which he usually puts before the shareholders. By building up their large reserve fund they had been able to duplicate all their lines at the expense of revenue, and, consequently, he ventured to think that their position was better than it had ever been. As to the competition, one never knew in these days when it was going to break out. The Chairman was usually so cautious that he never looked as if he were over sanguine, but he (the speaker) was glad to hear Mr. Andrews speak so hopefully of the future.

A SHAREHOLDER thought that the stationery account was too high and seemed to be rising every half-year, and urged on Major Wood to carefully look after the item of salaries and wages, which seemed too large for such a business as theirs. He thought, also, that the outlay in connection with their ships was amenable to reduction.

The CHAIRMAN said that such questions naturally arose in the mind of any shareholder, and they were very proper questions. He invited the gentleman who had spoken to go to the office of the Company and see the amount of work that was dealt with. Millions of messages were received and dispatched, and each message took not one form, but in its progress from end to end used up several. The stationery was one of the means of earning their revenue. It was stationery not merely used in this country, but over the whole of South America wherever the Company had stations, and it was mainly employed in the message work and in the abstract business of maps and publications of the Company, and when they came to see the work done they would not be surprised at the cost. When they sent out stationery to South America, it was sent in bulk because that reduced the expenses. They sent enough to last twelve or eighteen months, according to circumstances, and in some cases they sent a supply sufficient to last for three years, because of the cost of carriage and other things that had to be done. The charge looked heavy at the time, but it was economy in the end. As to the ships, it was a question of revenue that they should secure the safety and speedy repair of the lines. They had been keeping their eyes on the expenditure in regard to their ships, and not only so, but they had been in consequence able to put their hands on the sovereigns, and keep them in the till, and keep them there for the benefit of the shareholders.

A SHAREHOLDER thought that the expenditure, and particularly miscellaneous expenses, might be given in greater detail.

The CHAIRMAN said that they did not give as many headings as they could. What the shareholders wanted would be a still further analysis, if practicable. As to the miscellaneous expenses, they included all kinds of little outlays, which it would be well nigh impossible to set out. Even if they could be particularised, it would not be worth while to do so.

The resolution was then put to the meeting, and carried unanimously.

Mr. PETO proposed, and Mr. LIDDON seconded, a vote of thanks to the Chairman, his colleagues, and the chief officers of the Company.

The vote was passed, and

The CHAIRMAN having briefly returned thanks, the proceedings terminated.

Aluminium Company (Limited).

The fifth ordinary general meeting of this Company was held on Monday at the Cannon-street Hotel, under the presidency of Mr. G. W. Balfour, M.P.

The CHAIRMAN referred to the difficulties and disappointments which had attended the past career of the Company. When the Company was started, he said, the price of aluminium was 60s. per lb., and they expected, by means of their new process, that the cost price would be 10s. per lb., and that they would be able to command the market of the world at something like 20s. per lb. At the present time, however, aluminium, instead of being 60s., was to be obtained at 2s. per lb. They were obliged, then, to confess that they could no longer hold the field against the electrical methods of manufacture, and to bid farewell to the expectations of large profits they had anticipated. They had succeeded in creating a new branch of industry. It was true the trading account still registered an adverse balance, though a comparatively small one; but during the half-year from January to June the works at Oldbury showed a profit of between £2,000 and £3,000, and this was earned in the face of large reductions in the selling price of sodium. They had at the present time orders actually on hand that would keep the whole of their plant in operation for upwards of three months. With regard to the issue of £12,000 new debentures, they would be secured as a first charge on the new process, and as a second charge on the assets of the Company generally. With respect to the writing down of their capital, the matter had been fully considered by the Directors, and in their last report they stated that it would be ultimately necessary to do this. The only question was when it should be written down, and by how much. The Directors advised the shareholders to defer it until the value of the new electro-chemical process, invented recently by Mr. Castner (Managing Director), and to which they attached great importance, could, to a certain extent, be ascertained.

The report was adopted.

West India and Panama Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended 30th June last to be submitted to the thirty-first ordinary general meeting, to be held at Winchester House, on Tuesday, the 15th inst., at 12 o'clock:—

The amount to credit of revenue is £44,148. 17s. 7d., against £47,641. 16s. for the corresponding half-year of 1891, and the expenses have been £28,589. 6s. 4d., against £24,868. 16s. for the same period in 1891, leaving a balance of £15,559. 11s. 3d, which, with £2,122. 16s. 5d. brought from ast account, makes a total of £17,682. 7s. 8d., with which it is proposed to deal as follows:—

First Preference Shares—			
Dividend, six months to June 30th, 6s. per share..	£10,368	18	0
Second Preference Shares—			
Dividend, six months to June 30th, 6s. per share..	1,400	14	0
Ordinary Shares—			
6d. per share (free of income-tax)	2,208	0	6
Balance to current half-year's account	3,704	15	2
	£17,682	7	8

The traffic receipts for the six months show a decrease of £3,762. 3s. 11d. as compared with the corresponding period. This decrease is due to the reduction of tariff made in June last year.

The cost of repairs to cables amounted this half-year to £22,879. 0s. 10d., as compared with £11,936. 14s. 2d. for the corresponding period. Of this

Hosted by Google

sum £8,528 has been charged against reserve. The increased expenditure is due to the number of interruptions and to the laying in of greater lengths of new cable to renew and strengthen the system. The most difficult repairing operation, included in the above expenditure, was that of the Jamaica-San Juan section, where the fracture was in a depth of 2,234 fathoms. Owing to this great depth of water the old cable broke frequently in the attempts made to lift it to the surface, and this necessitated an expenditure of 85 knots of new cable to bridge over the gap.

The Company's s.s. "Grappler" has been ordered to London to be surveyed, in accordance with Lloyd's requirements, and to be fitted with a new boiler. She will return to the West Indies with a cargo of 256 nautical miles of cable for stock.

It will be in the recollection of shareholders that it was announced at the general meeting held in May that the Board had to regret the loss of their valued colleague, Mr. Ford, whose death had occurred since the issue of the report then submitted. Sympathy with his family and appreciation of the value of his services to the Company were expressed at the meeting. The Board, from motives of economy, do not propose to fill up the vacancy.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

BILLERICAY GAS COMPANY (LIMITED).—Capital £5,000, in £5 shares. This Company includes among its objects the business of supplying electric light, heat and power.

GLAUBER-FERRITE SYNDICATE (LIMITED).—Registered with a capital of £25,000, in £10 shares, to carry on the business of manufacturers of glauber-ferrite and of the plant, machinery and materials therefor, and to carry on the business of civil, mechanical, and electrical engineers.

LONDON MICA IMPORTERS (LIMITED).—This Company has been registered with a capital of £70,000, in £1 shares, to purchase and work mica mines, and to deal in mica generally.

NORTH AMERICAN CONSTRUCTION COMPANY (LIMITED).—A Company, under this title, has been registered, with a capital of £100,000, in £1 shares, to carry on (amongst other objects) electric light, telephone, telegraphic, and power supply works, &c.

STEPHANITE FLUX SYNDICATE (LIMITED).—This Company has been registered with a capital of £5,000, in £10 shares, to carry on the business of manufacturers of, and dealers in, an aluminium flux called "stephanite," and all aluminium and other alloys, and also the business of chemical manufacturers, metallurgists, &c.

W. WEEKS AND SON (LIMITED).—This Company has been registered with a capital of £25,000, in £5 shares, to carry on the business of mechanical and electrical engineers, iron and brass founders, &c., at the Perseverance Iron Works, Maidstone, Kent.

CROMPTON AND COMPANY (LIMITED).—The annual return of this Company, made up to August 12, 1892, has been filed. The nominal capital was at the time of making up £190,000, divided into 30,000 preference and 8,000 ordinary shares of £5 each, when 25,467 preference and 8,000 ordinary shares were taken up, and of these the ordinary shares were issued as fully paid to the vendors or their nominees (John F. Albright 2,432 shares and R. E. Crompton, 5,568 shares). Upon 20,000 of the preference shares the full amounts were called, upon 5,219 preference shares £2 per share called, and upon the remaining 248 preference shares £1 per share was called, resulting in the payment of £120,730 (which includes the payment of £10,044 in full).

HANLEY (STAFFS.) ELECTRICITY SUPPLY COMPANY (LIMITED).—This Company is to be dissolved.

J. C. HOWELL (LIMITED).—The statutory return of this Company, made up to November 1, 1892, has been filed. The Company was registered on July 9, 1892, with a capital of £25,000 in £5 shares. By an agreement of August 26, 1892, the Company acquired the said business in consideration for £10,000, which was fully satisfied by the allotment of 2,000 fully paid-up shares. At the time of making up 2,907 shares had been taken up, of which 2,000 had been issued as fully paid. Upon the remaining 907 shares the full amount had been called, resulting in the payment of £4,510 and leaving £25 as yet in arrears.

LINEFF ELECTRIC TRACTION AND LIGHTING SYNDICATE (LIMITED).—The annual return of this Company, made up to October 5th, has been filed. The Company was registered on August 8, 1888, with a capital of £10,000, in £1 shares, to acquire, introduce, work, and develop patents Nos. 8,380 and 13,447, of 1887. The patents were acquired by the Company for £8,003, which was fully satisfied by the allotment of 8,003 fully paid-up shares. At the time of making up 9,131 shares had been taken up, of which 8,003 shares had been issued as fully paid in accordance with the above agreement. Upon the remaining 1,128 shares the full amounts had been called, and all calls had been paid. The principal subscribers are Edward H. Bayley (3,396), J. Seymour Keay (3,932), Ann Batchmanoff (1,200), and Robert Applegarth (600).

LIVERPOOL SILVER AND COPPER COMPANY (LIMITED).—The annual return of this Company has been filed. The Company was registered in 1889 with a capital of £50,000, in £10 shares, to carry on the business of treating, by electrical or other processes, smelting, refining, converting, reducing, or assaying gold, silver, copper, or other ores and metals, and the manufacture of wire sheets and other forms of copper and copper alloys. At the time of making up all the shares had been taken up, £7 per share called, and all calls paid (£35,000).

LONDON AND HAMPSTEAD BATTERY COMPANY (LIMITED).—The statutory return of this Company has been filed. The Company was registered on May 13, 1892, with a capital of £50,000, divided into 7,000 preference and 3,000 ordinary shares of £5 each. At the time of making up 457 preference and 3,000 deferred shares had been taken up, of which the deferred shares had been issued as fully paid to Alfred W. Armstrong, the vendor. Upon 157 preference shares the full amount had been called, and upon the remaining 300 preference shares £2 per share had been called, resulting in the payment of £1,335, leaving £50 in arrears.

MAQUAY SYNDICATE (LIMITED).—A notice has been filed that at an extraordinary general meeting of the members of the above Company, held at 9, Frith-street, Soho, on August 27th, a resolution was unanimously passed (and at a subsequent extraordinary general meeting was duly confirmed), "That the Syndicate be wound up voluntarily under the provisions of the Companies' Acts, 1862 and 1867, and that Mr. Thomas Rawlins, of 45, King William-street, London, E.C., chartered accountant, be appointed liquidator." The Company was registered in September, 1889, with a capital of £12,000, in £100 shares. At the time of the last return (December 25, 1891) 92 shares had been taken up, of which 60 had been issued to Sir Edward R. Sullivan, Bart. (51), and Samuel W. Maquay (9), the vendors. Upon the remaining 29 shares the full amounts had been called, resulting in the payment of £2,550, leaving £350 in arrears.

NATIONAL TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to June 30, 1892, was filed on October 17th following. The Company was registered on March 10, 1881, with a capital of £600,000, divided into 15,000 preference shares of £10 each, and 90,000 ordinary shares of £5 each, to unite the businesses of the United Telephone Company (Limited) and the Provincial Telephone Company (Limited). The capital is now £4,000,000, divided into 30,000 preference shares of £10 each, and 740,000 ordinary shares of £5 each. At the time of making up, all the preference and 454,747 of the ordinary shares have been taken up, the full amounts called or considered as paid, and all calls (£2,573,735) paid. An agreement dated October 10th between George Gilmore, of Douglas, Isle of Man, and this Company, provides for the sale to the Company of the business and effects of the vendor relating to telephones, including the telephone exchange carried on by him, the benefit of all contracts with the subscribers to that exchange, the fittings, cables, wires, receivers, &c., in consideration for £2,100, which was to be satisfied by the payment of £1,500 in cash and the remainder in fully-paid ordinary shares.

CITY NOTES, &c.

CALLS DUE.—*Nov. 15:* CITY OF LONDON ELECTRIC LIGHTING COMPANY, £2 on 20,000 Cumulative Six per Cent £10 Preferences. *Nov. 21:* NOTTING HILL ELECTRIC LIGHTING COMPANY, £2 on 2,998 Preferences of £10.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The Stock Exchange Committee have ordered the further issue of 9,848 ordinary shares, Nos. 70,153 to 80,000, to be quoted in the Official List.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended November 6 were £891, as against £783 for the corresponding period of last year, being an increase of £108. The total receipts for half-year amount to £15,163, against £13,756 in the corresponding period of 1891, being an increase of £1,407.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the month of October were £2,307, against £2,436 for the corresponding period last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of the Company for the month of October amounted to £61,069 and to £60,784 in the corresponding period of last year, an increase of £285.

ELMORE'S.—The *Daily Chronicle* of yesterday contains the following:—"The Secretary of the Elmore's Patent Copper Depositing Company (Limited) has issued a circular to the shareholders, stating that the accounts of the Company for the past year are now in course of preparation, and will be shortly submitted to them. Since the date of the last general meeting the process has, it is stated, undergone further important developments, which have been brought to a thorough state of perfection. A thorough reorganisation has taken place with regard to the management of the business, and it has been considered necessary for the effectual control of the Company's affairs that the offices and books should be removed to Leeds, and that the Board meetings should be held at the works[!]. To facilitate this change, three of the London Directors [names not given] have retired in favour of two gentlemen resident in the Midlands, who have agreed to join the Board, both of the Elmore's Patent Copper Depositing Company, Limited, and the Elmore's Wire Manufacturing Company, Limited. The two new Directors—Mr. Terah Hooley and Mr. William Goode Johnson—have lately acquired a very considerable interest in the companies, one of them holding over 10,000 shares."

Hosted by Google

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for October amounted to £24,000, and from January 1st to October 31st to £223,600. In the corresponding months of 1890 and 1891 the amounts were £232,800 and £237,800 respectively.

REUTER'S TELEGRAM COMPANY.—An error occurred in a City Note in our last issue referring to the application made by this Company to the Stock Exchange Committee to appoint a settling day. The amount should have been 1,000 shares of £8 each, instead of £1,000 in shares.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts for the two weeks ended October 31st show an increase of £67, as compared with the corresponding period. The traffic receipts for the two weeks ended 15th October, 1892, were £2,072, and not £2,470, as previously published.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Nov. 4, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,834.

REGISTERED TRADE MARK.

THE "EXCELSIOR" WICK CARBON,

PATENTED IN ALL COUNTRIES BY

W. GRUDELBACH, Dinslaken-on-Rhine, GERMANY.

Each Carbon is stamped "EXCELSIOR"—none genuine without it.

THESE CARBONS ARE SUPERIOR TO ALL OTHERS, and, being made solely by a DRY PROCESS, offer the greatest advantages to consumers.

WILL NOT MAKE MUSHROOMS while burning.

DO NOT REQUIRE TO BE DRIED OR ANNEALED, and therefore the Wicks do not fall out.

THE WICK DOES NOT SHRINK nor form hollows, producing gases, and consequent flickerings.

LEAVE NO ASH, and give a steady white light (not blue) of the brightest description.

ARE MORE DURABLE THAN ANY OTHER CARBONS ON THE MARKET.

For further particulars address—

"EXCELSIOR" CARBON CO., 80, QUEEN VICTORIA STREET, LONDON, E.C.

JOHN TULLIS & SON, GLASGOW.

CONTRACTORS TO THE MOST IMPORTANT ELECTRIC COMPANIES AT HOME AND ABROAD.

ORANGE TAN LEATHER offers the following ADVANTAGES:—

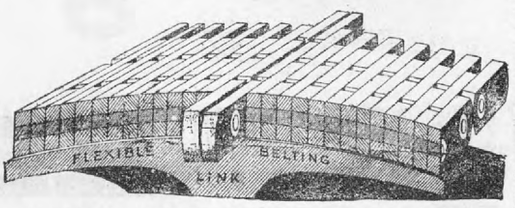
It possesses **more life** than any other Belt in the market.

It is **stretchless** and takes a **splendid grip** of the pulley.

It can carry with ease **one-third more load** than other leather.

It is **very thin** and **pliable**, and for **small diameters, fast speeds**, and **heavy work**, no other leather can compare with it.

Breaking strain (Lloyd's Proving House): **Orange Tan, 8,244lbs.** **Oak Tan, 5,746lbs.** per square inch.



17 HIGHEST AWARDS AT INTERNATIONAL EXHIBITIONS.

Where the one pulley is **flat** and the other **round**, this Belt will **easily accommodate itself** to either pulley, while at same time it will transmit the **maximum power.**

MOST TRUSTWORTHY BELT for ELECTRIC DRIVING.

We beg to call attention of belt users to a perusal of our Illustrated **GUIDE TO BELT-DRIVING,** *which we will send gratis on demand.*

—THE—

INDIA RUBBER, GUTTA PERCHA AND TELEGRAPH WORKS CO., LIMITED.

ELECTRICAL ENGINEERS,

AND

INDIA RUBBER AND GUTTA PERCHA MANUFACTURERS.

MANUFACTURERS OF

CABLES, WIRES, INSTRUMENTS, INSULATORS, DYNAMO MACHINES, MOTORS, ARC LAMPS & FITTINGS, BATTERIES, CARBONS, TORPEDO APPARATUS.

SPECIALITY.—Underground Electric Light System for High and Low Tension. The only System which has given complete satisfaction.

Contracts entered into for the Erection and Equipment of Central Lighting Stations, the Lighting of Ships, Factories, Houses, and the Supply of Complete Plant for Electrical Traction and Transmission of Power.

VULCANISED INDIA RUBBER.

HOSE, DRIVING BANDS, STEAM PACKING, WATERPROOF GARMENTS and FABRICS, SHOE SOLES, MATS, VALVES, BRAKE BLOCKS, WHEEL TYRES for CABS, CARRIAGES, BICYCLES, &c. SHEET, WASHERS, BUFFERS, SPRINGS, TUBING, SOLID CORD, FOOTBALL BLADDERS, LAWN TENNIS BALLS. MOULDED GOODS to any Pattern.

EBONITE.

Not affected by Vinegar or Hydrochloric or Acetic Acid.

SPECIALITIES IN EBONITE FOR CHEMICAL WORKS.

INSULATORS, BATTERY CELLS, SPEAKING TUBES, SHEET & ROD, SURGICAL APPLIANCES, PHOTOGRAPHIC ARTICLES, SCREW STOPPERS, PUMPS.

GUTTA PERCHA.

TUBING, BELTING, BUCKETS, BOSSES for FLAX SPINNING, GOLF BALLS, SHEET and TISSUE.

ESTIMATES & PRICE LISTS ON APPLICATION.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 757.—Vol. XXX. FRIDAY, NOVEMBER 18, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6.

NOTES.

The sad fatality on the 9th instant is the first case in this country of the death of a workman while engaged in work upon high-pressure electric conductors. On January 3, 1887, a fire broke out in Regent-street, either in the transformer closet or near it, and a man went on the roof and cut the wires with a pair of shears. A moment later he fell through a skylight a distance of 60ft. There was no evidence to show that he received a shock. On March 7th last a tailor's salesman at Chatham, seeing sparks coming from a transformer, attempted "to beat out the fire" with an iron bar, and received a fatal shock. In one sense these were accidents, and though at Chatham the insulation was undoubtedly defective the fatal result was not directly due to this fault.

The accident at Brompton, on the other hand, occurred under ordinary conditions of everyday work, and in spite of precautions, which a coroner's jury deemed to be sufficient. The Supply Company is protected by the following letter, of which Mr. Gay has, at our request, sent us a copy :—

The House-to-House Electric Light Supply Company (Limited).
Central Electric Lighting Station (Kensington),
Richmond-road, S.W., June 24, 1892.

Mr. Lang. Works.

Sir,—Under no conditions must any part of any high tension main be touched while the current is on, and no work of any description to be done on the mains or instruments connected therewith without using the rubber gloves provided for that purpose.

Great care must be taken to see that these gloves are in proper condition before using.—Yours faithfully,

(Signed) H. W. Bowden, Assistant Manager.

It appears that the current was turned off at 11 a.m., and was turned on again at 3 p.m. The accident occurred after 4 o'clock. The inconvenience of working in rubber gloves, and the temptation to discard them, may be compared with the use of the Davy lamp by coal miners. By long practice with rubber gloves it may be possible to do something more than haul at a cable, but they are a nuisance, even for such work as that, and it is no wonder that the men do not wear them. The real causes of the accident appear to have been due to the continuing of the work after the current was on, and the non-observance of the rule about wearing gloves. The fault on the cable was a matter of comparatively small importance, the leak would soon have been discovered in the usual way, and such defects are sure to occur sooner or later. It would be better to assume that such bad places are common. In the management of fiery coal mines and powder magazines a letter to each *employé*, together with verbal cautions, would hardly be considered sufficient; nor would an elaborate code of rules be of much value unless they were enforced by careful superintendence.

It will be remembered that Prof. Ewing showed two forms of his magnetic curve-tracing instrument at Edinburgh during the meeting of the British Association. One of these was arranged for moveable test bars, and the other was provided with a fixed core of soft iron wire. The curve-tracer, illustrated in another column, is of the second type, but it has passed from the rough experimental form into a very neatly designed and symmetrical instrument. No description of the rotary commutator used with this apparatus has previously been published. The most obvious use of this curve-tracer is for lecture purposes, or class demonstrations, but we confidently expect to find that some interesting additions to our knowledge of the magnetic properties of iron will be made by means of it, especially if mechanical improvements can be introduced to allow higher speeds to be used. Prof. Ewing has probably given careful consideration to this point, and the difficulties in the way of projecting a fair-sized diagram on a screen at a high speed are considerable. An inspection of the diagram of the mirror and aluminium cradle suggests that the dimensions of this essential part of the apparatus might be greatly reduced if the projection were abandoned, and the image observed by a microscope, as in the original form of Lissajous' experiment. Any new phenomena thus observed might be photographed with low amplification, and afterwards enlarged. Helmholtz, it will be remembered, examined the vibrations of stretched strings by observing through a microscope the movements of a brightly illuminated starch grain fixed to the string.

Independently of Prof. Ewing, and we understand before he had constructed the early form of his curve-tracer, Mr. Searle had drawn magnetisation curves by means of an instrument recently described by him before the Cambridge Philosophical Society. In his apparatus a vertical wire is suspended in galvanometer fashion, and is turned on the axis of suspension by a needle fixed to the upper end of the wire while the lower end carries a fork, in which a mirror is strung on a horizontal axis. The control being feeble, the system must be allowed to come to rest between successive readings

Hosted by Google

(about five seconds is sufficient), and a curve with 30 points may be described in about five minutes. For lecture purposes the spot of light may be taken round in about one-and-a-half minutes.

A GALVANOMETER recently shown to the Physical Society was, if we remember aright, described as of the Ayrton-Mather-Deprez-d'Arsonval type, and as it contained a mirror, the name THOMSON ought to have been added. We illustrate in another column a dynamo and engine, which should, by the same process, be called a Parsons-Ewing-Tesla-Gordon-Lontin-Muirhead-Hopkinson-high-frequency-turbine-combination. MUIRHEAD and HOPKINSON were, we believe, the first to use the zigzag winding, LONTIN used radial magnets and armature coils, TESLA largely increased their number, GORDON constructed a cone of boiler plate. Without a Parsons' engine to run it at 12,000 revolutions per minute, 14,000 complete cycles per second could not have been achieved, and it remained for EWING to cast the whole together. This is not called invention nowadays; nor was he the designing engineer, for how can a professor be an engineer? (See our Correspondence Columns.) But for EWING it would not have been built, that is safe; and but for Messrs. C. A. PARSONS and Co. it would not have been presented to the Engineering Laboratory at Cambridge.

OF the many experimenters who have investigated the fusing current of wires, none have taken into account the conditions which so greatly modify the result with such care as Herr C. FELDMANN. In ordinary practice, the size of the terminals is of considerable importance, and reliance placed upon the fusing point of long wires will lead not only to errors, but errors which are in the direction of danger. In another column we print a diagram prepared by Herr FELDMANN, to show the fusing current for any length and diameter of a given material, and clamped between terminals of given dimensions. By arranging special scales of length and diameter, the lines from which the co-efficients are found become straight. In such diagrams, interpolation between any two co-ordinates is rather difficult, especially for small values, but as the result has to be determined by interpolation between two of the slanting lines, only an approximation can be arrived at. In several other respects this form of diagram presents advantages.

IN commenting upon the driving of a loom by an electric motor, some time ago, we briefly discussed the application of motors to cotton-spinning machinery. After throwing out the suggestion that there was ample choice for the electrical engineer between one motor for each mule, or smaller ones at higher speeds, mounted on the carriages and driving the tin rollers direct, we made the very safe estimate that one-third, if not one-half, of the power at present expended might be saved. A Paper, by Mr. ALFRED SAXON, was read recently before the Manchester Association of Engineers upon "The Comparison of Friction in Cotton Mill Engines and Gearing to the Actual Work Done." In this Paper, of which we give an abstract in another column, the author appears to have compared the indicator diagrams of certain engines under full load and the same engines when running light. For the purpose in view he is no doubt justified in taking the difference between these two quantities as the "percentage of friction and total load," while this percentage deducted from 100 leaves "actual work done."

CAREFUL mechanical engineers, such as he from whom a quotation is given at the beginning of Mr. SAXON'S Paper, would hesitate to accept this mode of reckoning the efficiency, for several reasons into which we need not enter; but it must be admitted that an analysis of the different kinds of friction, of the differently resolved stresses, and of the behaviour of the steam would be extremely difficult, and would not, perhaps, materially alter the general result. About one quarter of the indicated power was spent on the engines and gearing (the main gearing only, we presume), the remaining 75 per cent. going to "friction in the machinery itself and the work done by the machinery." The distributing shafting appears to have been included as "machinery." This Paper makes, then, the first step in an inquiry which should be of great interest to those who are engaged in the construction of electric motors, and the determination of the power spent on the separate machines is a matter which could be settled without much difficulty by some of our Midland technical colleges.

WHETHER the distribution of power from a direct-driven dynamo to each machine in a cotton mill would pay or not depends largely upon the ratio of the cost of coal to the other manufacturing expenses. The enthusiasm, which we hope to share some day, about the utilisation of Niagara seems to be based upon the idea that, not only is the cost of coal so great that an enormous capital may be safely expended in supplying a cheaper source of energy, but that cheap power is such a *desideratum* that new industries and manufactures will be attracted to a district within which such power is available. If coal is of this importance in cotton spinning it must be worth while to save it. Shafting is cheap enough, and belts have wonderful lives in textile work, under careful management. The question practically becomes merely one of interest on dynamos and motors against cost of coal wasted on friction.

ABOUT this time last year we published an account of some experiments, by Prof. J. J. THOMSON, on the electrical oscillations induced in vacuum tubes. Certain tests made in connection with magnetic materials showed that iron and similar substances remained magnetic even for such rapid oscillations. Some of the numerous experiments made by Dr. LODGE, to account for the action of lightning rods, can also only be explained by supposing that the magnetism of iron is capable of following extremely rapid changes of magnetic force. We publish this week an account of some work of M. V. BJERKNES, which offers independent evidence confirming this conclusion. The object of the research was to investigate the rate at which the energy in Hertz resonators is dissipated in heat, and it was found that, for non-magnetic wires, this rate depends

Hosted by Google

merely on the resistance of the wire, and is independent of the nature of the material. With magnetic substances, however, a different law holds, and these results are in accordance with the theoretical conclusions of OLIVER HEAVISIDE and Lord RAYLEIGH, who showed that the magnetic nature of the material causes an increase of what is known as the "skin effect" occurring in all conductors through which rapid alternating currents pass. The increase in the resistance of the conductor, due to the crowding of the currents to the surface of the metal, was first shown experimentally by Prof. HUGHES, and forms the explanation of many of the results of Dr. LODGE. M. BJERKNES has investigated this effect in a most ingenious way, and his results are conclusive in showing that iron remains magnetic under the action of very rapid magnetic forces.

Coventry.—Mr. Graff Baker is negotiating with the Town Council for equipping the tramway system of the town with electric cars.

Hopkinson v. St. James and Pall Mall Electric Light Company.—The hearing of this case is expected to be resumed on Tuesday next.

Whitehaven.—The Local Government Board has sanctioned the borrowing of £14,000 for purposes of electric lighting, to be repaid within a period not exceeding 20 years from the date of borrowing.

Bristol.—At their meeting last week the Town Council resolved, without discussion, that the area included in Schedule B in the Bristol Electric Lighting Order, 1883, should be added to the area of supply under the said Order.

Electric Traction in Chicago.—The Westinghouse Electric Manufacturing Company have signed a contract with the Chicago City Railway Company for the complete equipment of 61 cars with single-reduction motors; also for four 200 H.P. generators.

The Protection of Buildings from Lightning.—Some five-and-twenty lightning rods guard the Louvre against the depredations of lightning. It is reported that only one is in good order, the remaining four-and-twenty being either discontinuous or disconnected from earth.

National Telephone Company.—The National Telephone Company are making rapid strides in the Newcastle district. From August 1st to October 31st 123 subscribers have been added to the system, making the total number in the northern district at the latter date 2,375, or on Tyneside only, 886.

Presentation.—The *employés* of the New Telephone Company at Manchester recently presented Mr. G. J. Somerville, the late Manager, with a silver tea service. Mr. Somerville is leaving Lancashire, where he has managed the Manchester Exchange since its opening, to take charge of the Company's metropolitan district.

Personal.—Mr. H. F. Lewis, of the National Telephone Company, and for several years Manager and Secretary of the late Western Counties and South Wales Telephone Company, has, it is stated, been appointed General Manager to the London Electric Supply Corporation, and takes up his new duties at the beginning of next month.

Chesterfield.—At a special meeting of the Town Council last week, it was decided, by ten votes to seven, to apply for an Electric Lighting Provisional Order, "so that, whether they went in for supplying the town with electricity or not, they would be in a position to avert any monopoly, and to make terms with any company which might approach them on the subject."

Magnetische Induktion.—We have received from Herr Julius Springer, of Berlin, a copy of Prof. Ewing's "Magnetic Induction in Iron and Other Metals," which has been translated into German by Dr. L. Holborn and Dr. St. Lindeck. We notice that in an appendix a description is given of Prof. Ewing's curve-tracer, and of the du Bois magnetic balance, with illustrations.

Proposed Tubular Railways.—It is intended to proceed during next session with a Bill for the construction of an underground electric railway from Paddington to South Kensington. It is understood that the promoters of the Bill believe that the scheme has been so altered as to meet the objections raised last year. It is intended to extend the subway to Clapham Junction, passing under the Thames at Chelsea.

Fire in Regent Street.—A fire broke out at about 4 o'clock on Wednesday morning in one of the windows of the London Stereoscopic Company's premises. The official report states that it was due to "overheat of electric wires." We learn from the St. James' and Pall Mall Company that the wiring was noted in their books as good, and our inquiries on the spot failed to elicit anything to support the suggestion that the fire was due to electrical causes.

Ceara-Maranham	November 9, 1892

The London Telephone System.—Mr. Barrs has placed the following motion on the agenda paper of the London County Council:—"That it be referred to the General Purposes Committee to consider and report whether the Council has powers to establish and work a telephone system in London similar to the system established and worked by the municipalities of Christiana, Liverpool, Manchester, and other towns; and, if so, to consider and report as to the desirability of exercising such powers." It may be worth while observing that not one of the municipalities referred to works—the telephone?

Huddersfield.—The work in connection with laying the electric light mains, which has been done in a most substantial and careful manner, has made very satisfactory progress, and is now nearly completed, there being 2,900 yards of conduit laid for the high pressure mains, 3,550 yards of conduit laid for the low pressure mains, and 64 junction boxes. The occupiers of a number of shops and offices have already applied to be connected to the mains. Some very advantageous positions have been secured for the transformer stations which are now in course of erection, and will be soon completed. By the spring of the coming year the electric supply will be commenced.

Taunton.—At a special meeting of the Town Council on Friday last the following resolution was passed by 14 votes to 1:—"That application be made to the Board of Trade for a Provisional Order under the Electric Lighting Acts, 1882 and 1888, authorising the Mayor, Aldermen, and Burgesses of the Borough of Taunton to supply electricity for public and private purposes within the said borough, and also within the Rural Sanitary District of the Taunton Union, or some part thereof, and that the Town Clerk be authorised to take the necessary steps for carrying this resolution into effect, and that the corporate seal be affixed to the memorial to the Board of Trade and all other documents relating to the application."

The Late Mr. Graves.—The remains of the late Mr. Graves were interred at Hammersmith Cemetery on Saturday noon last, in the presence of a large concourse of friends who had assembled at the grounds, in addition to the mourners who rode in the funeral *cortége* from Earl's Court. At the gates of the cemetery the procession was met by a detachment of Royal Engineers employed by the Post Office and the crew of the Department's cable-ship "Monarch," the whole falling in with the civilians who immediately followed the coaches. Divisonal engineers, besides higher officials, past and present, of the Postal Telegraph Service, and representatives from many tele-

Hosted by Google

graph construction and engineering firms attended in considerable numbers.

The Electric Lighting of the Guildhall.—The electric lighting at the Guildhall, says the *City Press*, naturally attracted particular attention on the 9th. "The Library installation will clearly need some alteration, the lamps in the bays shedding a sufficient light on the books below, but leaving the rows above in almost absolute darkness. If these lamps, instead of being suspended in the middle of the bays, were raised a few feet higher, and arms were projected from the lower shelves, every part, including the tables, would be sufficiently illuminated. Even then we could not fail to remark that the Library installation is exceedingly plain as compared with the installations in the Council Chamber at Guildhall, which is really beautiful, the electroliers being most artistically coloured and designed."

Engineering at Cambridge.—The following letter from Prof. J. A. Ewing appeared in *The Times* of Monday :—

"The report of 'University Intelligence' which appears to-day (Friday) in *The Times* omits an item of sufficient consequence to excuse my asking you to give it this publicity. Amongst the 'graces' voted yesterday were three which have the effect of establishing a Tripos of Mechanical Science. The new tripos has been framed in the interests, especially, of engineering students, its purpose being to allow them to follow a curriculum of study in mathematics, mechanics, and the theory of engineering of the kind most appropriate to men who are afterwards to adopt the profession of engineer. The first examination in the new tripos will be held in 1894, and I am glad to say that a good number of students have already begun to prepare for it. The scheme was adopted by the Senate without opposition or even criticism. It would be a pity, however, if the very unanimity with which it has been received were to prevent the public from being made aware that a tripos in engineering is now an accomplished piece of University legislation. The University is appealing for subscriptions to enable it to supply what is yet lacking in the way of engineering laboratories. Meanwhile it has taken a step of vital importance in the development of its engineering school by making a scientific training in engineering form one of the avenues to its honours degree."

The Drilling of Telegraph Messengers.—The new Postmaster-General is said to be giving much encouragement to the arrangements, which are now taking permanent form, for the drilling of telegraph messengers in London. More than 3,000 messengers are distributed over the metropolitan districts, and 1,000 of these are drilled alternately every third week. Nearly 500 boys from the Central Telegraph Office, the Eastern Central district, and the Eastern district, whose duties do not begin until after 10 a.m., paraded early Thursday morning last week, and marched to the Tower, where they were put through certain military evolutions and physical drill in the presence of the Postmaster-General, who subsequently addressed the lads. He announced that the Department was arranging a system of prizes as rewards for proficiency at drill and general smartness. With Mr. Arnold Morley were Mr. J. C. Lamb, assistant-secretary, the controllers of the Central Telegraph Office and the London postal service, several district postmasters, and other of the higher officials of the Department.

The Hydrophone.—The Portsmouth correspondent of *The Times* states that Capt. M'Evoy's ingenious telephonic apparatus for defending roadsteads, anchorages, and minefields, by giving warning by visible and audible signals on shore of the approach at night, or during thick weather, of torpedo boats or other hostile vessels, has just been subjected to experiments extending over several weeks at the mining establishment in Stokes Bay, where it was witnessed in operation by Col. Vetch, of the War Department, a committee of Royal Engineers from Chatham, and various officers belonging to H.M.S. "Vernon." The instrument is called a hydrophone, and consists of two parts. One part is placed on the sea bottom at a depth of from 5 to 15 fathoms, and the other is fixed in a station on the shore. In the present instance the instrument was sunk in 7 fathoms and about 300 yards off Fort Gilkicker. The submerged part consists of a bell-shaped iron case, three-quarters of an inch thick, 20in. in height, and extreme diameter, and weighing about 340lb. At the top a diaphragm is fitted. No sooner does a boat approach within a radius of half-a-mile or so than the pulsations of her propeller produce a vibratory movement inside the case, which is transmitted electrically to the shore. The whole of the operations were successfully performed in the presence of the visitors. It is contended, also, that another field of operations is open to hydrophones in dangerous zones around certain headlands.

Electric Light Fatality.—An inquest was held on Monday last at the Kensington Town Hall concerning the death of T. P. Lang, aged 23 years, an *employé* of the House-to-House Electric Lighting Company, who was killed by an electric shock on Wednesday last week. David Young said that Lang was working with him on the day in question in Roland-gardens, Brompton-road. Lang was in a box, and the witness signalled to him to draw in the slack of a 7/21s. cable after a joint had been made on a service wire. Lang drew it about a foot and then suddenly stopped. The witness looked and saw him lying over the hole, and immediately procured a pick and broke the wire. Only half a minute elapsed from the time when the witness noticed the deceased until the time he broke the cable. The current was on at the time. He did not notice if there was any rubber between Lang's hand and the wire. Mr. H. W. Bowden, engineer and assistant manager to the Company, said that he had examined the cable and had no hesitation in saying that it was a cable that any man could safely work on with the current on, but he thought that while the man was pulling the cable out, he must have come to a part where the rubber was off the wire. The part of the cable where it touched the man's hand was bare. He could not say whether the rubber was removed before the accident, or by the heat of the man's hand. The current was at a pressure of 2,000 volts. The men were supposed to use rubber gloves, and a letter was sent to Lang on June 24 cautioning him against touching any of the wires without using the gloves provided. If Lang had worn the gloves the accident could not have occurred. Dr. H. A. Clowes said the deceased was dead when admitted to the Jubilee Hospital. The palm of the hand and the two first fingers of his left hand were charred and burned. There was no burning or singeing of other parts of the body. There was a marked fluidity of blood throughout the body, but there was not a clot of any sort. The jury returned a verdict of "Accidental death," and exonerated the Company from all blame.

The Telephones and Electric Traction.—The case of the Hudson River Telephone Company against the Watervliet Turnpike and Railroad Company was decided at the end of last month by the New York Court of Appeal. The Telephone Company complained of injuries to its system due to the adoption of the single trolley system. The Court stated that the Telephone Company was not using the streets for one of the purposes to which they had been dedicated as public highways, while the Turnpike Company was using them in such a manner as to expedite public travel. The Telephone Company was there by virtue of a legislative grant, revocable at the pleasure of the power that created it, and it was a part of its contract with the State that the maintenance of its lines of communication should not prevent the adoption by the public of any safe and expeditious mode of transit. It was found that the Turnpike Company's use of electricity in the propelling of its cars rendered the operation of the Telephone Company's telephones at all times difficult and sometimes impracticable, and this disturbance could not be avoided by the Turnpike Company without a complete change of the system adopted by it. To require such change to be made would be to grant to the Telephone Company that which the Legislature had expressly withheld. But the Telephone Company was exposed to another danger. The Turnpike Company allowed the electric current to escape directly into the ground, and the most serious loss which the Telephone Company sustained resulted in the current spreading upon the Telephone Company's grounded wires. The Court was not prepared to say that a person, even in the prosecution of a lawful business upon his own land, could gather there by artificial means a natural element like electricity and discharge it in such a volume that, owing to the conductive properties of the earth, it would be conveyed upon the lots of his neighbour with such force as to interfere with the rightful enjoyment of the use of his property, and not be liable for the damages resulting therefrom. Still, it was not required in this case to decide that point. For these reasons the previous decision in favour of the Telephone Company was set aside.

ELECTROMAGNETIC THEORY.—XXXIX.

BY OLIVER HEAVISIDE.

(*Continued from page 663, Vol. XXIX.*)

§ 171. The reader of Prof. Tait's profound treatise on Quaternions will probably stick at three places in particular, to say nothing of the numerous minor sticking-points that present themselves in all mathematical works of any value, and which may be readily overcome by the reader if he be a real student as well. First, there is the fundamental Chapter II., wherein the rules for the multiplication of vectors are made to depend upon the difficult mathematics of spherical conics, combined with versors, quaternions and metaphysics. Next, Chapter IV., where the reader may be puzzled to find out why the usual simple notion of differentials is departed from, although the departure is said to be obligatory. Thirdly, Chapter V., where the reader will be stopped nearly at the beginning by a rather formidable investigation of Hamilton's cubic. Only when the student is well acquainted with the nature of linear operators and how to work them can he tackle such an investigation. He should, therefore, pass on, to obtain the necessary experience. On then returning to the cubic he may find the investigation not so difficult after all, especially if it be simplified by some changes calculated to bring out the main points of the work more plainly.

The reader is led to think that the object of the investigation is to invert a linear operator—that is, given $\mathbf{D}=c\mathbf{E}$, to find $\mathbf{E}=c^{-1}\mathbf{D}$. But if this were all, it would be a remarkable example of how not to do it. For the inversion of a linear operator can be easily effected by other far simpler and more natural means. The mere inversion is nothing. It is the cubic equation itself that is the real goal. The process of reaching it is simplified by the omission of inverse operations. (It is also simplified by not introducing the auxiliary function called χ.)

The fundamental cubic is derived from equation (105), or the equivalent equation (110) last investigated. I should remark that this equation is frequently useful in advanced vector-analysis as a transformation formula, turning $\mathrm{V}c\mathbf{mcn}$ to a function of $\mathrm{V}\mathbf{mn}$. Now use the form (110), or

$$x\mathrm{V}\mathbf{mn}=c'\mathrm{V}c\mathbf{mcn}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (111)$$

where x is a known function of c, viz.,

$$x=\frac{c\mathbf{l}\mathrm{V}c\mathbf{mcn}}{\mathbf{l}\mathrm{V}\mathbf{mn}}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (112)$$

Here c is any linear operator. Now if g be a constant, $g\mathbf{m}$ is a linear function of $\mathbf{m}$, and therefore $(c-g)\mathbf{m}$ is any linear function of $\mathbf{m}$; that is, $c-g$ is a general linear operator. Equation (111) therefore remains true when we substitute $c-g$ for c in it, not forgetting to make the change in x, and also the equivalent change in c', viz., from c' to $c'-g$. Equation (111) then becomes

$$x_g\mathrm{V}\mathbf{mn}=(c'-g)\mathrm{V}(c-g)\mathbf{m}(c-g)\mathbf{n}, \quad (113)$$

where x_g is what x becomes by the change, that is, by (112),

$$x_g=\frac{(c-g)\mathbf{l}\mathrm{V}(c-g)\mathbf{m}(c-g)\mathbf{n}}{\mathbf{l}\mathrm{V}\mathbf{mn}}. \quad . \quad . \quad (114)$$

Remembering that g is a constant, we may readily expand (113) to the form

$$\begin{aligned}&(x-x_1g+x_2g^2-g^3)\mathrm{V}\mathbf{mn}\\&=c'\mathrm{V}c\mathbf{mcn}-g(\mathrm{V}c\mathbf{mcn}+c'\mathrm{V}\mathbf{mcn}+c'\mathrm{V}c\mathbf{mn})\\&\quad-g^3\mathrm{V}\mathbf{mn}+g^2(c'\mathrm{V}\mathbf{mn}+\mathrm{V}\mathbf{mcn}+\mathrm{V}c\mathbf{mn}), \quad . \quad . \quad (115)\end{aligned}$$

where the cubic function of g on the left side is the expansion of x_g. The new coefficients x_1 and x_2 are, of course, to be found by expanding (114), but we do not want their values immediately. Since x is a function of c only, x_g is a function of c and g only, so that x_1 and x_2 are functions of c only.

Now since (111) is an identity, so is (115); and since g may have any value, the last equation must be identically true for every power of g concerned, taken one at a time. That is, it splits into four identities. Now, on comparing the coefficients of g^0 on the left and right sides, we obtain (111) again. Similarly, we observe that the coefficients of g^3 are the same. So far, then, we have nothing new. But the g and g^2 terms give

$$x_1\mathrm{V}\mathbf{mn}=\mathrm{V}c\mathbf{mcn}+c'(\mathrm{V}\mathbf{mcn}+\mathrm{V}c\mathbf{mn}), \quad . \quad . \quad (116)$$

$$x_2\mathrm{V}\mathbf{mn}=c'\mathrm{V}\mathbf{mn}+(\mathrm{V}\mathbf{mcn}+\mathrm{V}c\mathbf{mn}), \quad . \quad . \quad . \quad (117)$$

which are fresh identities. From these various others may be deduced by elimination or combination. The one we are seeking is obtained by operating on the first by c' and on the second by c'^2, and then subtracting the second result from the first. This eliminates the vector in the brackets and leaves

$$(x_1c'-x_2c'^2)\mathrm{V}\mathbf{mn}=c'\mathrm{V}c\mathbf{mcn}-c'^3\mathrm{V}\mathbf{mn}, \quad . \quad (118)$$

$$=(x-c'^3)\mathrm{V}\mathbf{mn}, \quad . \quad . \quad . \quad (119)$$

where the transition from (118) to (119) is made by using (111) again. Rearranging, we have the final result,

$$(x-x_1c'+x_2c'^2-c'^3)\mathrm{V}\mathbf{mn}=0, \quad . \quad . \quad . \quad (120)$$

which is Hamilton's cubic. Note that $\mathrm{V}\mathbf{mn}$ may be any vector we please, and may, therefore, be denoted by a single letter. Observe, also, that the cubic function of c' is of the same form as that of g in the expansion of x.

Since (120) is true for all linear operators, we may write c instead of c', giving

$$x-x_1c+x_2c^2-c^3=0. \quad . \quad . \quad . \quad . \quad (121)$$

This form is what we should have arrived at had we started from (105) instead of (110). The value of x is the same in either case, and it may be inferred from this that x_1 and x_2 do not suffer any change when we pass from a linear operator to its conjugate.

That the complex function x_g is independent of $\mathbf{l}$, $\mathbf{m}$, $\mathbf{n}$, may be seen by inspecting (114), and observing the parallelepipedal form of numerator and denominator. For, suppose we alter $\mathbf{l}$ to $\mathbf{l}+a\mathbf{m}$, where a is any constant. The addition made to the numerator vanishes by the parallelepipedal property, and similarly in the denominator. The same invariance obtains when we change $\mathbf{l}$ to $\mathbf{l}+a\mathbf{n}$. But, unless $\mathbf{l}$, $\mathbf{m}$, $\mathbf{n}$ are coplanar, we may turn $\mathbf{l}$ to *any* vector by adding to it vectors parallel to $\mathbf{l}$, $\mathbf{m}$ and $\mathbf{n}$ of the right size. Therefore, x_g is the same whatever vector $\mathbf{l}$ may be. By the same reasoning $\mathbf{m}$ may be any vector, and so may $\mathbf{n}$. But $\mathbf{l}$, $\mathbf{m}$, $\mathbf{n}$ should be independent vectors (that is, not coplanar). This is not because we can suppose that an actual discontinuity occurs when (for example) $\mathbf{l}$ is brought into the plane $\mathbf{m}$, $\mathbf{n}$, but merely because the expression x_g assumes an indeterminate form in the coplanar case.

From the invariance of x_g follows that of the three functions it contains, namely, x, x_1, and x_2. That of x, of course, may be independently seen by itself, readily enough, but that of the others is less plain, because on expansion they are found to each involve three parallelepipedal products in the numerator instead of only one. Thus, expanding (114) we obtain

$$x_1=\frac{\mathbf{l}\mathrm{V}c\mathbf{mcn}+\mathbf{m}\mathrm{V}c\mathbf{ncl}+\mathbf{n}\mathrm{V}c\mathbf{lcm}}{\mathbf{l}\mathrm{V}\mathbf{mn}}, \quad . \quad (122)$$

$$x_2=\frac{c\mathbf{l}\mathrm{V}\mathbf{mn}+c\mathbf{m}\mathrm{V}\mathbf{nl}+c\mathbf{n}\mathrm{V}\mathbf{lm}}{\mathbf{l}\mathrm{V}\mathbf{mn}}. \quad . \quad . \quad (123)$$

In these we may, by the above, substitute c' for c, that is, turn the linear operator to its conjugate. This does not mean that x_g is independent of the vector $\mathbf{a}$ which comes in when the operator is not symmetrical, but that it only involves $\mathbf{a}$ quadratically.

The value of x being

$$x=c_1c_2c_3+\mathbf{aca}, \quad . \quad . \quad . \quad . \quad . \quad (124)$$

expressed in terms of the principal constants of the symmetrical operator and the rotation vector, we may obtain the reduced values of x_1 and x_2 from it directly instead of from their general expressions. Thus: turn c to $c-g$ (in 124), making it

$$x_g=(c_1-g)(c_2-g)(c_3-g)+\mathbf{a}(c-g)\mathbf{a}. \quad . \quad (125)$$

On expansion, the coefficients of g and g^2 show that

$$x_1=c_2c_3+c_3c_1+c_1c_2+\mathbf{a}^2, \quad . \quad . \quad . \quad (126)$$

$$x_2=c_1+c_2+c_3.$$

Thus x_2 is independent of $\mathbf{a}$, whilst x_1 involves its square, as we concluded previously.

Hosted by Google

When referred to the principal axes, Hamilton's cubic therefore reduces to

$$0 = (c_1c_2c_3 + \mathbf{a}c\mathbf{a}) - (c_1c_2 + c_2c_3 + c_3c_1 + \mathbf{a}^2)c \left.\begin{matrix}\\ \\ \end{matrix}\right\} + (c_1 + c_2 + c_3)c^2 - c^3, \left.\begin{matrix}\\ \\ \end{matrix}\right\} \quad (127)$$

and in the symmetrical case of vanishing $\mathbf{a}$ to

$$0 = (c - c_1)(c - c_2)(c - c_3). \quad . \quad . \quad . \quad (128)$$

Here the axes are coperpendicular. But we may disregard the principal axes altogether, and write the general cubic in the form

$$0 = (c - g_1)(c - g_2)(c - g_3), \quad . \quad . \quad . \quad (129)$$

where the g's are the roots of $x_g = 0$. If, then, these roots are all real and different, there are three directions of parallelism of $\mathbf{r}$ and $c\mathbf{r}$, or three $\mathbf{r}$'s such that

$$c\mathbf{r}_1 = g_1\mathbf{r}_1, \qquad c\mathbf{r}_2 = g_2\mathbf{r}_2, \qquad c\mathbf{r}_3 = g_3\mathbf{r}_3. \quad (130)$$

Now multiply the first by $\mathbf{r}_2$ and the second by $\mathbf{r}_1$, giving

$$\mathbf{r}_2c\mathbf{r}_1 = g_1\mathbf{r}_1\mathbf{r}_2, \qquad \mathbf{r}_1c\mathbf{r}_2 = g_2\mathbf{r}_1\mathbf{r}_2 \quad . \quad . \quad . \quad (131)$$

The left members are not usually equal, but in the symmetrical case they are, and then the right members are equalised. Then $\mathbf{r}_1\mathbf{r}_2 = 0$, or $\mathbf{r}_1$ is perpendicular to $\mathbf{r}_2$. Similarly $\mathbf{r}_2$ is perpendicular to $\mathbf{r}_3$. This is the case of three mutually perpendicular axes of parallelism of force and flux we started from.

§ 172. If we write c^{-1} for c in the cubic (121) we see that $c^{-1}\mathbf{r}$ becomes expressed as a function of $\mathbf{r}$, $c\mathbf{r}$, and $c^2\mathbf{r}$. This is one way of inverting the operator, but a very clumsy way. The simple way is in terms of dyads, and is fully described by saying that if

$$c = \mathbf{a.l} + \mathbf{b.m} + \mathbf{c.n} \quad . \quad . \quad . \quad . \quad (132)$$

is any linear operator in dyadical form, then its reciprocal is

$$c^{-1} = \mathbf{L.A} + \mathbf{M.B} + \mathbf{N.C}, \quad . \quad . \quad . \quad (133)$$

where $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$ is the set complementary to $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$, and $\mathbf{L}$, $\mathbf{M}$, $\mathbf{N}$ the set complementary to $\mathbf{l}$, $\mathbf{m}$, $\mathbf{n}$. We have already used these complementary vectors in the early part of this chapter, equations (54) and (55), § 114. We showed by elementary considerations that any vector $\mathbf{r}$ could be expressed in terms of any three independent vectors $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$ by

$$\mathbf{r} = \mathbf{rA.a} + \mathbf{rB.b} + \mathbf{rC.c}, \quad . \quad . \quad . \quad (134)$$

where the complementary vectors $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$ are got from $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$ by

$$\mathbf{A} = \frac{\mathrm{V}\mathbf{bc}}{\mathbf{a}\mathrm{V}\mathbf{bc}}, \qquad \mathbf{B} = \frac{\mathrm{V}\mathbf{ca}}{\mathbf{a}\mathrm{V}\mathbf{bc}}, \qquad \mathbf{C} = \frac{\mathrm{V}\mathbf{ab}}{\mathbf{a}\mathrm{V}\mathbf{bc}}. \quad (135)$$

These equations serve to define the set complementary to $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$. We also showed at the same time that the vector $\mathbf{r}$ could be expressed in terms of the complementary set by

$$\mathbf{r} = \mathbf{ra.A} + \mathbf{rb.B} + \mathbf{rc.C}. \quad . \quad . \quad . \quad (136)$$

To verify, we have merely to multiply (134) by $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$ in turn, and (136) by $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$ in turn.

These equations may be written

$$\mathbf{r} = (\mathbf{a.A} + \mathbf{b.B} + \mathbf{c.C})\mathbf{r}, \quad . \quad . \quad . \quad (137)$$

$$\mathbf{r} = (\mathbf{A.a} + \mathbf{B.b} + \mathbf{C.c})\mathbf{r}, \quad . \quad . \quad . \quad (138)$$

showing that the dyadic in the brackets is of a very peculiar kind, inasmuch as its resultant effect on any vector is to reproduce the vector. That is, taken as a whole, and disregarding its detailed functions, the dyadic is equivalent to unity.

Now, suppose it is given that

$$\mathbf{R} = (\mathbf{a.l} + \mathbf{b.m} + \mathbf{c.n})\mathbf{r}, \quad . \quad . \quad . \quad (139)$$

so that $\mathbf{R}$ is any linear function of $\mathbf{r}$. We know that

$$\mathbf{R} = (\mathbf{a.A} + \mathbf{b.B} + \mathbf{c.C})\mathbf{R}, \quad . \quad . \quad . \quad (140)$$

and that

$$\mathbf{r} = (\mathbf{L.l} + \mathbf{M.m} + \mathbf{N.n})\mathbf{r}, \quad . \quad . \quad . \quad (141)$$

by the property of the complementary vectors explained. Comparing (140) with (139), we see that

$$\mathbf{lr} = \mathbf{AR}, \qquad \mathbf{mr} = \mathbf{BR}, \qquad \mathbf{nr} = \mathbf{CR}. \quad . \quad (142)$$

Using these in (141), we convert it to

$$\mathbf{r} = (\mathbf{L.A} + \mathbf{M.B} + \mathbf{N.C})\mathbf{R}, \quad . \quad . \quad . \quad (143)$$

comparing which with (139), we see that the inversion of the dyadic has been effected in a simple and neat manner.

Professor Gibbs calls the vectors $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$ the reciprocals of $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$. They have some of the properties of reciprocals. Thus,

$$\mathbf{aA} = 1, \qquad \mathbf{bB} = 1, \qquad \mathbf{cC} = 1; \quad . \quad . \quad . \quad (144)$$

and in Gibbs's language $\mathbf{a}$ and $\mathbf{A}$ are reciprocal. But it seems to me that the use of the word reciprocal in this manner is open to objection. It is in conflict with the obvious meaning of the recipocal $\mathbf{a}^{-1}$ of a vector $\mathbf{a}$, that it is the vector whose tensor is the reciprocal of that of $\mathbf{a}$ with unchanged ort (or with ort reversed in the quaternionic system). It will also be observed that Gibbs's reciprocal of a vector depends not upon that vector alone, but upon two others as well. It would seem desirable, therefore, to choose some other name than reciprocal. I have provisionally used the word "complementary" in the above, to avoid confusion with the more natural use of "reciprocal."

§ 173. In connection with the dyadic, it should be remarked that we have only employed them in the manner they usually present themselves in physical mathematics, namely, so as to make scalar products with the vectors they are associated with. But there is also the vector product to be consided in a complete treatment. Thus,

$$\mathrm{V}\phi\mathbf{r} = \mathbf{a}.\mathrm{V}\mathbf{l}\mathbf{r} + \mathbf{b}.\mathrm{V}\mathbf{m}\mathbf{r} + \mathbf{c}.\mathrm{V}\mathbf{n}\mathbf{r}, \quad . \quad (145)$$

$$\mathrm{V}\mathbf{r}\phi = \mathrm{V}\mathbf{r}\mathbf{a}.\mathbf{l} + \mathrm{V}\mathbf{r}\mathbf{b}.\mathbf{m} + \mathrm{V}\mathbf{r}\mathbf{c}.\mathbf{n}. \quad . \quad (146)$$

Observe that, as before with the scalar products, the vector $\mathbf{r}$ only combines with the vectors nearest to it in the dyadic, and not separated from it by the dots. Notice, too, that whereas the scalar product $\phi\mathbf{r}$ of the dyadic ϕ and a vector $\mathbf{r}$ is a vector; on the other hand, the vector products $\mathrm{V}\phi\mathbf{r}$ and $\mathrm{V}\mathbf{r}\phi$ are themselves dyadics, and behave as such in union with other vectors. Thus $\mathrm{S}\mathrm{V}\phi\mathbf{r}$ is a vector, and so is $\mathrm{S}\mathbf{r}\mathrm{V}\phi$, the first being got by making scalar products of $\mathbf{s}$ with $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$, and the second with $\mathrm{V}\mathbf{ra}$, &c. But to go further in this direction would be to go beyond the scope of the present treatment.

The differentiation of linear operators must, however, be mentioned, because the process is of frequent occurrence in electromagnetic investigations. If we think only of the differential coefficient of a scalar, that it is its rate of increase with some variable, it might seem at first sight that the differential coefficient of a linear operator was nonsense. But a little consideration will show that it is a perfectly natural, and by no means a difficult conception. Thus, from

$$\mathbf{D} = c\mathbf{E}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (147)$$

where c is a linear operator, we obtain, by differentiation with respect to a scalar variable, say the time,

$$\dot{\mathbf{D}} = \dot{c}\mathbf{E} + c\dot{\mathbf{E}}. \quad . \quad . \quad . \quad . \quad . \quad (148)$$

Here in the second term on the right we suppose that c is constant, and in the first that $\mathbf{E}$ is constant. The meaning of $\dot{c}\mathbf{E}$, then, is the rate of increase of $\mathbf{D}$ when c alone varies. It is the linear operator whose constituents are the rates of increase of the constituents of c. That this is so will be evident on differentiating the set of equations (79). Therefore, if

$$c = \mathbf{a.l} + \mathbf{b.m} + \mathbf{c.n}, \quad . \quad . \quad . \quad . \quad (149)$$

we shall have

$$\dot{c} = \dot{\mathbf{a}}.\mathbf{l} + \dot{\mathbf{b}}.\mathbf{m} + \dot{\mathbf{c}}.\mathbf{n} + \mathbf{a}.\dot{\mathbf{l}} + \mathbf{b}.\dot{\mathbf{m}} + \mathbf{c}.\dot{\mathbf{n}}, \quad . \quad (150)$$

the sum of two dyadics. But it may be that our axes of reference are invariable, as for example when

$$c = \mathbf{i}.c_1 + \mathbf{j}.c_2 + \mathbf{k}.c_3, \quad . \quad . \quad . \quad . \quad (151)$$

$\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$ being a fixed set of rectangular orts. Then we have the one dyadic

$$\dot{c} = \mathbf{i}.\dot{c}_1 + \mathbf{j}.\dot{c}_2 + \mathbf{k}.\dot{c}_3, \quad . \quad . \quad . \quad . \quad (152)$$

where, of course, the dots over the $\mathbf{i}$ and $\mathbf{j}$ do not signify any differentiation.

In an isotropic dielectric of variable permittivity the electric stress leads to the force $-\nabla_c(\frac{1}{2}c\mathbf{E}^2)$ per unit volume, where the scalar c alone is differentiated, so that the result is $-\frac{1}{2}\mathbf{E}^2\nabla c$.

Hosted by Google

But if the dielectric be eolotropic, the corresponding force is $-\nabla_c(\frac{1}{2}\mathbf{E}c\mathbf{E})$. This is equivalent to

$$-\tfrac{1}{2}\left(\mathbf{i}.\mathbf{E}\frac{dc}{dx}\mathbf{E}+\mathbf{j}.\mathbf{E}\frac{dc}{dy}\mathbf{E}+\mathbf{k}.\mathbf{E}\frac{dc}{dz}\mathbf{E}\right), \quad . \quad (153)$$

where dc/dx, &c., are differential coefficients of c as above explained. It means the same as

$$-(\nabla_D-\nabla\mathbf{E})(\tfrac{1}{2}\mathbf{E}\mathbf{D}), \quad . \quad . \quad . \quad . \quad (154)$$

where ∇_D means that **D** alone, and $\nabla\mathbf{E}$ that **E** alone is differentiated.

(To be continued.)

FUSE WIRES.

BY C. P. FELDMANN.

If for any set of terminals the fusing current for a fuse wire of given length, diameter, and substance be known, the current necessary to fuse a wire of any other length, or diameter, but of the same substance, and clamped between the same terminals, may be found as the product of two constants—$c = af$. The constant a is the current necessary to fuse a wire of unit length and unit diameter, and has to be found by previously experimenting upon any wire whose constant f is known. f itself is a function of the length l and diameter d of the wire, and may be taken from the accompanying diagram, the use of which is best explained by an example:

To find the constant f for a wire whose length $l = 25$ mms., and whose diameter $d = 1{\cdot}5$mms., follow a vertical line nearly midways between 1·4 and 1·6 till it intersects with the horizontal line marked 25. Near the point of intersection you will find a stout line marked $f = 0{\cdot}8$. This is the value

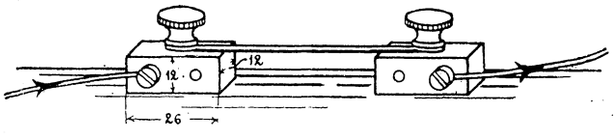

FIG. 2.

wanted. For the alloy which I tested,* and for the small terminals (Fig. 2), I found $a = 31{\cdot}6$ ($a^2 = 1{,}000$); for the large terminals (Fig. 3), I found $a = 36{\cdot}8$ ($a^2 = 1{,}350$). The fusing current would have been, for the small terminals,

$$c = 31{\cdot}6 \times 0{\cdot}8 = 25{\cdot}4 \text{ amp.},$$

and for the large terminals,

$$c = 36{\cdot}8 \times 0{\cdot}8 = 29{\cdot}4 \text{ amp.}$$

Of course a varies with the terminals, with the unit chosen to measure diameter and length, and with the substance of the fuse wire.

* *The Electrician*, Vol. XXIX., p. 87.

The diagram has been constructed by plotting as ordinates the $\sqrt[4]{e}$, and as abscissæ the $d^3/^2$. If for any special purpose the values shown in the figure should not be found suitable, the units of length and diameter may be changed so as to fit the scale of the diagram. *But it must not be forgotten that the constant a has to be changed, too, in a suitable manner, that is, it has to be determined by another experiment and for the new units chosen.*

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, November 18th.

INSTITUTION OF ELECTRICAL ENGINEERS.

7:30 p.m. Annual Dinner at the Criterion Restaurant.

MONDAY, November 21st.

SOCIETY OF ARTS.

8 p.m. Cantor Lectures. I., 1., "The Generation of Light from Coal Gas," by Prof. Vivian B. Lewes.

TUESDAY, November 22nd.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be discussed:—(1) "Halifax Graving Dock, Nova Scotia," by the Hon. R. C. Parsons, M.A.; (2) "Cockatoo Island Graving Dock, New South Wales," by E. W. Young, M.Inst.C.E.; (3) "The Alexandra Graving Dock, Belfast," by W. Redfern Kelly, M.Inst.C.E.; (4) "Construction of a Concrete Graving Dock at Newport, Monmouthshire," by Robert Pickwell, Assoc.M.Inst.C.E.

WEDNESDAY, November 23rd.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read:—'Cremation as an Incentive to Crime," by F. Seymour Haden, F.R.C.S.

THURSDAY, November 24th.

INSTITUTION OF CIVIL ENGINEERS.

2:30 p.m. Students' Visit to the Gas Light nd Coke Company's Chief Office, Westminster.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be read (in the event of the discussion on Mr. Swinburne's Paper being terminated):—"Experimental Researches on the Alternate Current Transformer," by Dr. J. A. Fleming, F.R.S.

FRIDAY, November 25th.

PHYSICAL SOCIETY

5 p.m. Paper to be read:—"Experiments in Electric and Magnetic Fields, Constant and Varying," by E. C. Rimington and E. Wythe Smith.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read The Telephone," by Howard Little.

Hosted by Google

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.* "THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.

NOW READY.

Volume XXIX. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad carriage extra.

Cases for binding Volume XXIX., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

CYRUS W. FIELD.

With "THE ELECTRICIAN" for Oct. 28 was issued a Fine Steel-Plate Portrait of the late CYRUS W. FIELD, Pioneer of Ocean Telegraphy. Copies can be supplied, price 1/0, on roller 1/2, post free.

THE SOCIAL EFFECTS OF ELECTRIC POWER SUPPLY.

At the time when the public supply of power by electric current was scarcely an accomplished fact, but when its immediate prospect called for speculation on every hand, it was a common thing to hear of the social and industrial revolution which the new power would inaugurate. The age of electricity, we were told, as contrasted with the iron age of steam and coal, would witness tremendous changes in the conditions of civilised life. Vast cities, grimy, foggy, colonies of labour, such as the Black Country, huge factories, would no longer be necessary. Every man would work during the day, as he would rest during the evening, "under his vine and under his fig tree." Electric supply would be laid on at every door, and power would be brought to the operative instead of, as before, the operative going to the power. Such was the dream, and such is undoubtedly the popular opinion even to-day; but what are the facts?

The chief influences which have tended to produce the present industrial system are the advantages accruing from a combination of capital, and the absolute necessity, in these days of fierce commercial competition, for cheap power, cheap labour, rapid transit during the stages of manufacture, and efficient supervision. In any industry involving several stages of manufacture, or requiring the use of expensive machinery and power on a large scale, it is impracticable to conduct each branch on a separate capital footing and in a separate establishment. The integration of the several processes under one commercial head is an evil it may be, but a necessary one, and it cannot be altered by electric supply, as this element does not affect the economic principle upon which the phenomenon is

Hosted by Google

based. Assuming, then, that some sort of factory system is needful, let us inquire into the possibility of carrying out the various processes of manufacture in a number of separate homesteads in place of in a large building. The necessity for cheap power at present compels the manufacturer to place all his machinery as closely together as possible, since steam power cannot be cheaply transmitted to a distance by shafting and belting. But will the advent of electric power revolutionise the present system? It would appear not. Even should the actual cost of power per unit supplied be the same for small as for large supplies, the prime cost of putting down machinery and wiring in a number of isolated houses would greatly exceed that for a large factory of the same power. Moreover, in some districts where electric power is to be supplied on the largest scale, the tariff is not fixed at the same rate for small as for large consumers. At Niagara, the Power Supply Company propose to charge an annual rental of $21 per horse-power for a 300-H.P. supply, but only $10 per horse-power for a 5,000-H.P. supply. It seems probable that some such sliding scale will be adopted by other electric power stations, even by those employing steam engines, when the experience of a few years shall have evolved the best working details of supply. But whether power is to be obtained on a sliding scale of charges or at a fixed rental per unit, the total cost of utilising that power in a large factory will be always less than that of utilising it in a set of isolated, decentralised homes. The idea of distributing power has great fascination to many minds. In its crudest form we find factories and power, or even a "floor with power" is frequently rented, energy being supplied by a shaft sticking through the party wall. Supply by compressed air has struggled fitfully in Paris, and engineers have never been wanting who could add just those improvements which were needed to make it a success. It has had a trial at Birmingham, where there are many small industries and a fair prospect of a good business. A large number of small steam plants are used in that city, and tests proved that these were very extravagant in steam, and that high insurance premiums were asked. But the initial expenses were greater, and the demand was less than was expected, the leakage was about 45 per cent. instead of the 20 which had been expected, the motors gave only about 30 per cent. efficiency without heating the air, and at the end of 1891 the Company was wound up.

If the cost of power is not to be reduced by the proposed change, how much less will be the reduction in the cost of labour. Consider the immense expense involved in distributing raw material to a number of isolated cottages, of passing on material from one cottage to another, and, finally, of collecting the finished article. Even the cheapest and most rapid system of electric transit will not make it simpler or better to have detached and distant houses rather than a compact single building. Consider, also, the expense and difficulty in superintending work on such a system. The workshop foreman will depart, and who or what is to take his place? Nor will the crowded city vanish any more rapidly than the close and (it is said) unhealthy factory life. The circumstances which combine to make it necessary or advisable for mankind to congregate in cities are even less affected by systems of engineering than are the circumstances which lead to factories. The long tentaculæ of electric power cables may reach out in every direction to the rural districts, offering power as cheaply there as in the towns, but the manufacturer who would prefer to build his factory at the far end of the cable rather than at the town end is yet to be found, unless, indeed, there were other and stronger inducements to adopt a rural site. In the aggregation of factories into industrial centres the commercial and market considerations outweigh the advantages of cheap land and labour; and, even should power be obtained for nothing in every part of the United Kingdom, the forces which build up great industrial cities would still be as effective as they now are.

What, then, may we reasonably expect to be the immediate social and industrial effects of the general introduction of electric power supply? Chiefly these. As regards city life, the generation of power at large central stations will enable a more efficient and rigid system of smoke abatement to be enforced; for at such stations it will be both easier and more economical to consume smoke than is the case in the innumerable small factories and private chimneys which now pollute the atmosphere. City life will become more healthy. Moreover, electric power will probably be used for every manner of private and public vehicle, which would largely eliminate the domestic horse, and, with him, much of the dust and mud which make our streets intolerable. Cities will become more clean. In small factories and industrial shops the introduction of electric power will substitute cool, convenient and silent electro-motors for noisy heat engines of various kinds, with their clumsy gearing. On the whole, therefore, it does not appear that any serious and immediate revolution in our industrial systems will follow the substitution of electricity for steam; but that many useful and pleasant changes of a less pretentious character will probably result.

REVIEWS.

Telephones: Their Construction and Fitting. By F. C. Allsop. Second Edition, 1892. (E. and F. N. Spon, London and New York.)

The rapid exhaustion of the first edition of this useful book is a surer test of its merits, from the publishers' point of view, than anything that can be said by its reviewers. Perhaps this very fact may afford the reviewer somewhat greater freedom in handling a book which, from his point of view, might have been made more to his liking in a second edition. That it has been enlarged, that the illustrations have been multiplied, and that the text has, to use the common phrase, been brought "up to date," may be taken as a matter of course when, as in this case, the subject-matter is closely related to a growing and constantly improving industry. We lose no time in saying, as to this, that the additions have been well done; and the "practical" character of the "treatise" thoroughly sustained. But we employ the term "practical" in the limited sense evidently intended by the author, that is to say, in a non-scientific sense. If, however, the author had been literally true to his intentions he would have omitted probably a sixth part of what he has written in explanation of the appliance with which he is dealing. It is nothing to the author's discredit, perhaps, that he is not himself quite master of the whole of his subject; but it would have been more to his credit if he had let one part of it alone. Whether the practical part of telephone "construction and fitting" can be rightly taught without a thorough knowledge of what, for want of a better phrase, we may call the scientific understanding of it, is a question we should hesitate to answer. But Mr. Allsop answers it himself by attempting at some length to make it understandable. In this he has not quite succeeded; and we rather think he might just as well have come to his "practical" treatment straight away without any pretence of scientific examination of first principles. They will be of little use to the "practical man" who wants to know what he has to do in given conditions; and still less to the theoretical or scientific student who wants to learn what the telephone essentially is. The book is profusely illustrated; and it would seem that illustrations are easy and cheap, while explanations are difficult and expensive. Many of these illustrations are of the trade catalogue order, pictorially pretty but devoid of instruction. What, for example, is the value of Fig. 41?—a microphone induction coil it is called; but for all the meaning it conveys,

Hosted by Google

it might be a drum or a reel of cotton. Yet the function of induction which comes into play at that stage of telephonic development is in need of the fullest explanation if the task of explanation be undertaken at all. In reality, it is shirked altogether, and the inquiring student is left with a bewildering impression that, although it is possible to erect a telephone line and connect up the apparatus in a "practical" way without knowing what it means, it is impossible to obtain an intelligible explanation of its operation—which is by no means the case. Having said this, however, we gladly give our tribute of praise to the painstaking care with which that portion of the work has been executed, which the author is thoroughly acquainted with. Here the diagrams, namely, those descriptive of connections, switches, exchanges and line constructions, are all that can be desired. As a guide to the practical man who desires to know what he has to do, without troubling himself about why he does it, this book may be frankly recommended as the best of its kind.

Magnetism and Electricity. By R. WALLACE STEWART, B.Sc. (University Correspondence College Press.)

This is a text-book, designed to assist students preparing for the examinations of the University of London. A new work of this kind should have some special pretension—something beyond the claims of the host of text-books already in existence—to recommend it; some new or modern discoveries or theories; some better mode of expressing old truths. In this work we can find no such *raison d'être*. There are far better, far more exact, text-books already in extensive circulation. The principal claim to consideration in books of this class seems to be the "cut and dried" way in which the information is served up for the student to swallow before going up for examination. Not that the author of this new text-book does not tell us anything new. On the contrary, there are statements which must be new to the most advanced electrician. In the section on Ohm's law, for example, we are told that—"The *law* involved is, perhaps, best explained by reference to the definition of resistance given in the preceding article. The resistance of a conductor is there defined as the ratio of the E.M.F. applied to the conductor to the current produced in it. Now, Ohm's law states that, assuming resistance to be defined in this way, the resistance of a given conductor is constant for all values of E and C; that is, a given conductor presents the same resistance to all currents, and is independent of the E.M.F. producing the current. Hence, combining our definition of resistance with Ohm's law, we may write $-C = \frac{E}{R}$, where C denotes the current produced by an E.M.F. E in a conductor of resistance R, and R is *assumed* to be constant for a given conductor." This, then, is the real *law!* A law which assumes what it is designed to prove, and which tells us that if R equals E over C, then C equals E over R. But this "law" is dead against Nature, for it is *not* true that the resistance of a given conductor is independent of the current flowing through it. As for the logic, it is all a piece of *petitionem principii per circulum;* a method of "reasoning" which, by-the-bye, crops up in other parts of the book. Now a book which cannot give a clear and correct account of so fundamental a matter as Ohm's law is untrustworthy as a student's text-book. In books of this class especially, where proofs are omitted and the student has to take things on trust, unless he *can* trust he is lost.

The author tends a little towards modern applications of electricity in the later portion of his work, and tells us that an arc lamp is a device in which "a strong current is forced by a powerful E.M.F. through a small air-gap," and "the air heated to incandescence is the source of light." A description and illustration of the obsolete Clark's dynamo is also given.

We very much regret to say that we cannot recommend this work as a student's text-book.

Uppenborn's Kalender, 1893. (Munich and Leipzig: R. Oldenburg.)

The tenth edition of this well-known Year Book is before us. While maintaining the original form, the editor has enlarged many of the sections, and the information given appears to be very complete; for instance, the question of dynamo design (from an electrical point of view) is carefully gone into, and curves are given by which the application of Hopkinson's methods is made easy. It seems, however, hopeless to convince people that standard curves for cast-iron are quite useless, owing to the enormous variations in the molecular and magnetic structure of the material. Among other information which does not, so far as we know, figure in any similar publication in this country, are details of German central stations, giving the output for which the stations are designed, the maximum load on any one day, and other information. The "Kalender," while not pretending to be an engineering work, is among the most complete note-books on purely electrical and physical subjects that we have seen.

THE EWING MAGNETIC CURVE-TRACER.

At a meeting of the Cavendish Physical Society, Cambridge, held last week, Prof. Ewing gave an exhibition of his magnetic curve-tracer, using a form of the instrument which has just been constructed by Messrs. Nalder Bros, with the object of allowing the magnetic cycle to be performed at a high speed. The instrument is shown in Fig. 1, which is engraved from a photograph. The magnetic circuit, whose variations of magnetism are exhibited, is arranged as a rectangle standing up from the base-plate, and supported by a post in the centre. It is laminated, consisting of a number of strips of thin sheet iron, of the kind used in transformer cores. The ends of these are securely clamped in a pair of wrought-iron pole-pieces on the base-plate, which is a slab of slate, and the poles have a narrow gap between them within which the stretched wire works which gives vertical motion to the mirror, proportional to the varying magnetism of the laminated circuit. A gun-metal casting, arranged in the form of a bridge, supports the compound lever by which the pivot of the mirror is supported, as well as the springs which serve to keep the connecting threads taut; and the same bridge piece forms a post for the support of the main magnet, and also carries the other electro-magnet, which consists of a piece of iron tube split longitudinally to form a slot for a second stretched wire, which gives horizontal deflection to the mirror, proportional to the magnetising force. It will be remembered that this result is secured by keeping the magnetisation of the tubular magnet constant, and by allowing the current which circulates in the magnetising coil of the main magnetic circuit to pass through the wire that is stretched in the slot of the tubular magnet. The pivot-point of the mirror is held by a system of two adjusting levers which are moved by milled-headed screws to give it two adjustments, vertical and horizontal, for the purpose of bringing the zero position of the spot of light to any desired point of the screen. The mirror itself is pivoted in the manner shown in Fig. 2. The mirror *a* is cemented to a little cradle *b* of aluminium, in which a small hole or rather recess is drilled just behind the mirror. Into this recess a needlepoint, held by the fixed piece *c*, enters. At the other side of the cradle two threads are attached, of which one, *d*, goes down to the vertically-moving wire in the gap of the variable magnetic circuit, and the other comes out, perpendicular to the plane of the paper, to the horizontally moving wire in the gap of the constant magnetic circuit. A pair of light spiral springs, of which one is indicated in the sketch at *e*, hold the threads taut and are set to rake back a little, so that they give a component of force pressing the mirror cradle against its pivot sufficiently to prevent it from slipping off.

The magnetic cycle is performed in one-tenth of a second or less, but so smoothly that the mirror is at no stage subjected to any jerk. This requires that the variations of magnetising current shall be continuous and gradual. An ordinary commutator with sudden makes and breaks of contact will not do, and the necessary smoothness is obtained by using a continuous commutator, the joint invention of Prof. Ewing and Mr. C. G. Lamb, which was described at the Cavendish Physical Society for the first time. The principle of the continuous commutator will be seen by reference to Fig. 3, which gives a sectional plan of the essential parts of the instrument. A cylindrical vessel of glass

Hosted by Google

or earthenware, containing a solution of sulphate of zinc, has two zinc plates, A and A′, fixed in it at diametrically opposite portions of the inner circumference. These plates are connected respectively to the two poles of a battery. A boss of non-conducting material nearly fills the vessel, leaving only a narrow clearance space round it for the sulphate solution. The boss is supported on a footstep, which allows it freedom to revolve, and is turned either by hand or by a pulley at the top

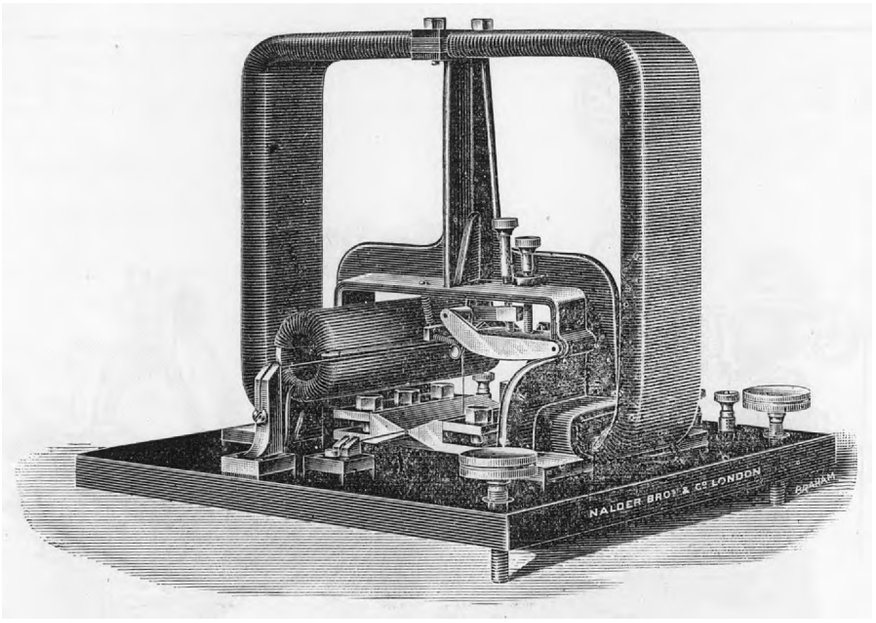

Fig. 1.—General View of the Ewing Magnetic Curve Tracer.

connected with an electric motor. A second pair of zinc plates, B and B′, are fixed to the boss itself, on opposite sides of its circumference. As the boss revolves the plates fixed on it take a potential difference approximating to that of the fixed plates, as they pass these; then a quarter revolution brings the potential difference gradually to zero, the next quarter revolution raises it gradually to a value equal and opposite to the first, and so on. The plates carried by the boss are connected to collecting rings on the vertical spindle, from which currents are led off through brushes to the magnetising coil of the magnetic curve-tracer. By having one of these continuous commutators placed in series with a

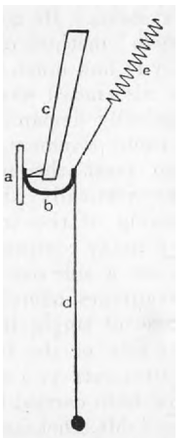

Fig. 2.—Suspension of Mirror in Magnetic Curve Tracer.

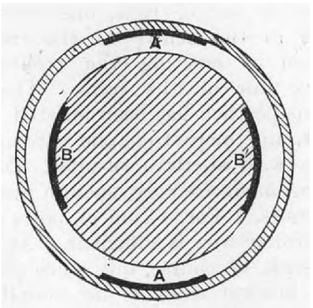

Fig. 3.—Continuous Commutator.

fluid resistance slide, to superpose a continuous reduction of the strength of the current on periodic changes on its sign. the experiment was shown of "demagnetising by reversals," in which the curve-tracer exhibited the cyclic process gradually diminishing its range until the area of the diagram vanished. The "Rayleigh" stage of the magnetisation, when a feeble force applied or reversed gives magnetic changes involving no hysteresis, was well shown in this way. A still more striking experiment consisted in placing two of the continuous fluid commutators in series, and turning one slowly or quickly by hand, while the other was left revolving uniformly at a high speed, when small loops appeared superposed on the principal cycle of magnetisation.

The main magnet of the instrument, shown in Fig. 1, is wound with two magnetising coils, which allow experiments to be readily made showing the influence exerted by a permanent magnetisation of any assigned value on the behaviour of the metal with respect to a supplementary force subject to cyclic variation, and on the amount of hysteresis which such a supplementary cycle involves.

THE EWING HIGH FREQUENCY ALTERNATOR.

The steam turbine combined with two dynamos on one shaft, which we illustrate, has been presented by Messrs. C. A. Parsons and Co., of Newcastle, to the Engineering Laboratory of Cambridge. Its chief point of interest is that one of the dynamos, designed by Professor Ewing, has a periodicity of 14,000 complete cycles per second at 12,000 revolutions per minute.

There are two distinct dynamos—one of the usual two-poled type, with a continuous current armature for an output of 15 amperes at 100 volts. This armature can be converted into an alternator by slipping two contact rings on the commutator, each ring being connected to diametrically opposite segments of the commutator and insulated from the others; the magnets being in this case separately excited. An output of 20 amperes at 40 volts, with a periodicity of 200 cycles per second, is obtained.

Professor Ewing's alternator is complete in itself, and is bolted on to a prolongation of the bedplate. The construction of the poles of the armature and field magnet is shown in Figs. 2 and 3. Fig. 2 is a part section and part elevation showing several poles *a a a* of the field-magnet, which revolves, and corresponding poles *b b b* of the laminated armature, which is stationary. Fig. 3 is a radial section. The poles *a a a* (140 in number) are made by toothing a pair of mild steel discs which are placed back to back, as is shown in Fig. 3, and the poles *b b b* are made by toothing a ring of 60 sheet iron plates, each about 10 mils thick, which are clasped together by a cast-iron supporting ring *c c*. The armature ring is bored $\frac{1}{32}$in. larger than the magnet disc and sawn radially by 140 cuts $\frac{3}{8}$in. deep. The winding of *a a a* is done with insulated copper strip, which is held from flying out by the projecting lip or fillet which appears on each side of the

Hosted by Google

poles in Fig. 3. The winding of the armature poles *b b b* is done with insulated wire of a considerably finer gauge than that shown in the illustration. Both windings are put on in zigzag fashion. The two discs into which the revolving field-magnet is divided are insulated from one another, and are used as conductors between the brushes by which the exciting current enters and the copper tape with which the teeth are wound. These two discs form mechanically a single disc of conical form, thickest near the axis to give it strength to resist the centrifugal force due to the high speed of rotation. The whole arrangement has the effect of reducing the revolving parts to the utmost simplicity—a matter of some consequence when the speed is 12,000 revolutions per minute.

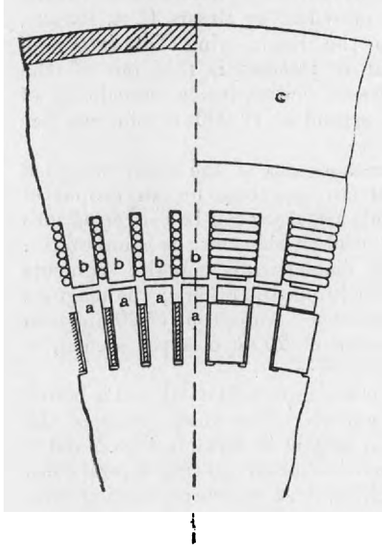

FIG. 2.

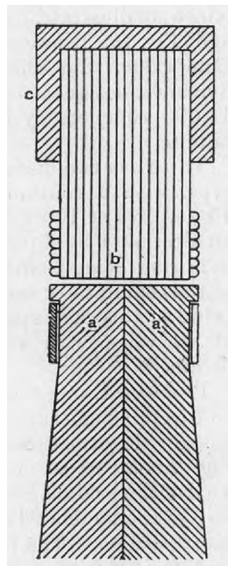

FIG. 3

Field Magnet and Armature Poles of Ewing High-Frequency Alternator.

It will be seen that there are 70 complete cycles of current per revolution, and at 12,000 revolutions per minute this gives 14,000 complete cycles per second. The output is about 5 amperes at 100 volts. It is, we believe, intended to carry out a series of experiments on the physiological effects of alternating currents of high frequency, as well as other interesting investigations.

ELECTRIC TRACTION ON THE SOUTH STAFFORDSHIRE TRAMWAYS.

The Electric Street Railway in South Staffordshire, between Walsall, Wednesbury, Bloxwich and Darlaston, deserves special mention. It is not only the first application of the trolley system paid for by English capital, but the details are boldly original and due to an English engineer who has attained to no little celebrity in the tramway world. Mr. Alfred Dickinson, the engineer to the South Staffordshire Tramway Company, has been the mainspring of the undertaking, and he is alone responsible for the many novel features and new departures from the received American practice. This gentleman visited the United States about two years ago and there made an exhaustive study of the "span" and "bracket" trolley systems. He noticed the many objectionable features of the "span" method of wiring, and felt convinced that it was not likely to find much favour in England. The "bracket" system he also noted was not applicable to small lines, because it practically demanded either a double set of rails, one close to each pavement, or else posts in the centre of the track to meet the invariable custom of erecting the trolley wire vertically above the centre line of the tram. The running of the trolley-rod in this position has been insisted on by many competent engineers, and more than one attempt to use a side-rod has been made with abortive results. The advantages offered by the arrangement are clear enough in the case of single lines with turn-outs. For, a line of posts on one side of the road with one trolley wire is sufficient. At the turn-outs two wires are required, of course, but since they are both carried from the same bracket there is no complication. Mr. Dickinson came back from America with this idea clearly fixed in his mind, and ultimately convinced his company of its feasibility. The objections raised to the trolley system on æsthetic grounds are no longer tenable, for the South Staffordshire line is really *far less prominent* than the telegraph poles and wires, which run parallel with it for a considerable part of the way. From the point of economy there can be little doubt that the side trolley-system is far superior to the vertical pole for long lines with light traffic. It should be noted that a trolley wire running vertically over the car is decidedly objectionable for outside passengers, since there is always a risk of injuring from falling wires. This does not matter very much in America where the

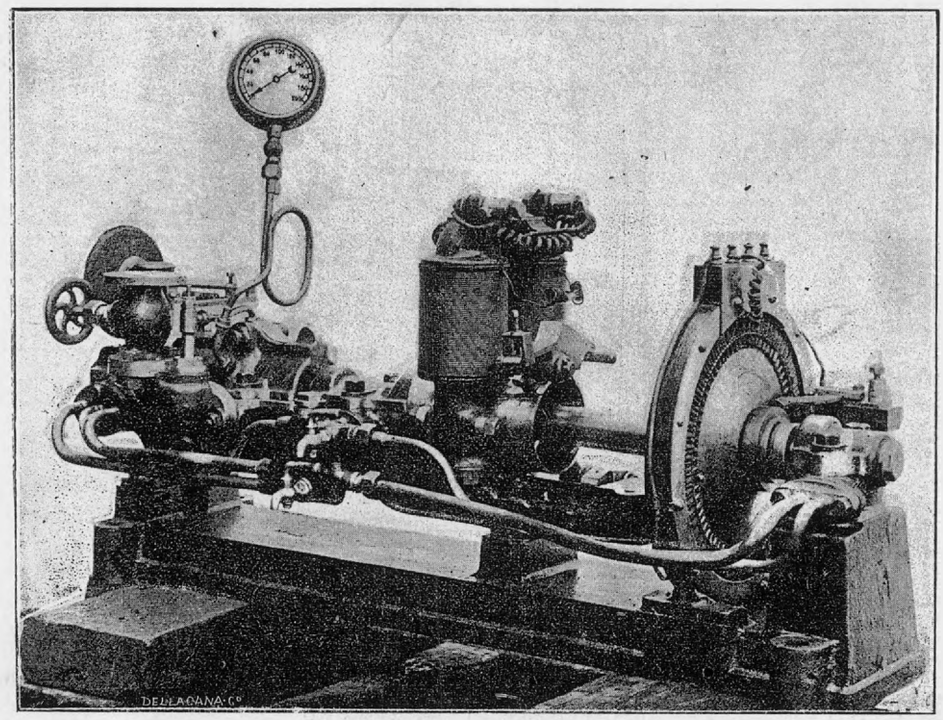

FIG. 1.—Parsons' Steam Turbine and Dynamos presented to the Cambridge Engineering Laboratory.

Hosted by Google

cars usually carry the passengers inside only; but it is of great importance in England, because outside seats are in such common use. The side trolley wire is, of course, entirely free from this objection, and this single point is likely to give it much favour with the travelling public. In crowded streets with two lines the double bracket centre post is, perhaps, advisable, particularly in very wide streets. But for narrow roads with double lines the side trolley will prove to be the cheaper and better.

We are indebted for the following particulars to the courtesy of Mr. Dickinson:—The circuit roughly resembles two Y's joined at the bases. The road from the Bull Stake is perhaps the least irregular in levels of any of the four, on which these trams run. It starts fairly level for about 150 yards, after which there is a rise for about 200 yards, of 1 in 40, followed by a long down gradient for 1,400 yards, of 1 in 56. After another sharp rise followed by an equally abrupt fall, there succeeds, for some 700 yards, a rise in the road of 1 in 60, and another down gradient of 1 in 75 completes this portion of the road at the Pleck. At this point there converges another line from the White Horse, which, commencing at the latter with a rising gradient of 1 in 36, succeeded by a fall for 2,000 yards of 1 in 60, the Pleck being reached in the course of a gentle rise of 1 in 150. The two lines just dealt with unite at the Pleck and run in one direction as far as Mellish Road. For some 700 yards the road maintains an average level, then succeeds for 900 yards a rise of 1 in 70, a fall of 1 in 28, and finally a fairly level section for about 1,200 yards. A line branching off from Walsall Bridge on the last section to Bloxwich, a distance of rather more than 2 miles, is a constant ascent for almost the whole distance, the average gradient being 1 in 90.

The power station is near Darlaston Station, on the London and North-Western Railway, and is not far from the centre of the system. The cars have been specially built to meet the conditions of a 3ft. 6in. gauge, and yet to carry a pair of 15 B.H.P. motors. The under-carriages (Fig. 1) are light and strong, and the pair of independent brakes are neatly fitted into the limited space. Room has also been found for two sand boxes, under the control of the driver. Some of the cars were built by Messrs. Brown, Marshall and Co., of Birmingham, and the remainder by the Lancaster Carriage and Wagon Company. They have excellent steel under-carriages, and the seats are arranged crosswise, inside as well as outside; a general view is shown in Fig. 2, and a sectional end elevation in Fig. 3. The motors are of the double-magnetic circuit type, with single reduction by helical gearing, the angle between the two sides of the teeth being about 130 deg. The pinions are 5¼in. in diameter, and the wheels 20¼in., the ratio of gearing being 1/3·87. The rolling wheels are 33in., so that a car speed of nine miles per hour will require 330 revolutions of the armature per minute. The armatures are drum-wound, and the brushes are of carbon. The design of the machines is substantially the same as that used by the Electric Construction Corporation at Birmingham. The speed is controlled by a rheostat, and a separate reversing switch is used. The trolley line posts are made entirely of rolled steel, and are particularly good examples of this class of work, being strong and yet elegant; the straining

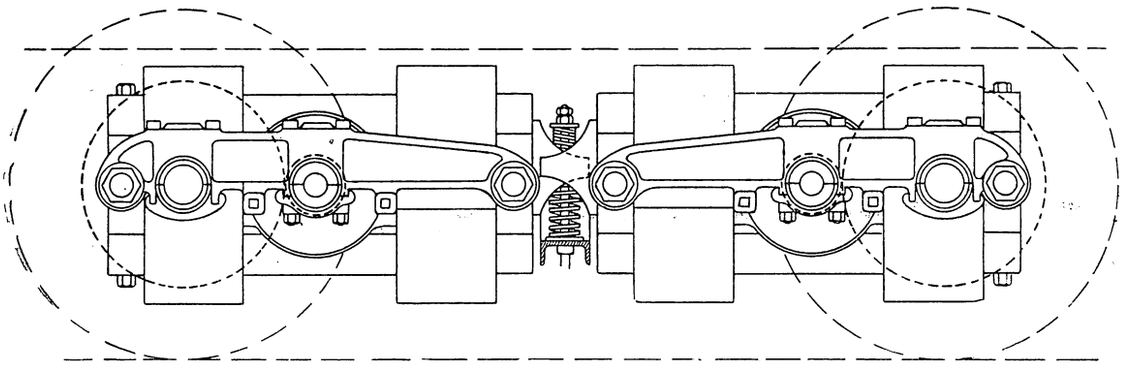

FIG. 1.—General View of Under Carriages and Motors.

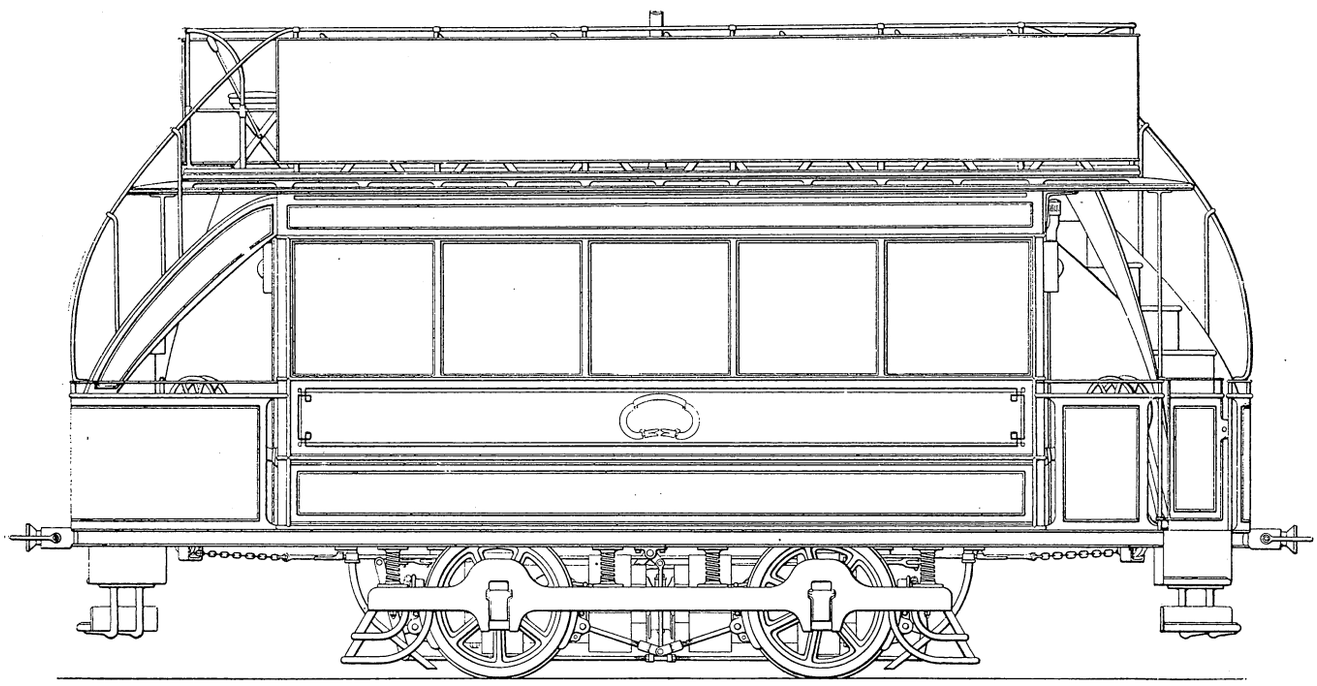

FIG. 2.—General View of Car.

Hosted by Google

posts, also used as lamp-posts, are specially worthy of notice. These were supplied by James Russell and Sons, of Wednesbury.

The trolley wire is 21ft. above the road level, and is No. 00 gauge. It is carried by specially devised compressed mica insulators. The feeders are laid underground, and are coupled to the "line" at intervals of half a mile. Each of these junctions has a switch so arranged that either of the two sections can be disconnected for testing or other purposes. The "line" turnouts at the passing places are made in brass, with frogs for leading the trolley wheel on the up line, and with springs for letting the wheel run through on the down line. They are thus automatic, and, though so simple, are evidently the outcome of much thought and careful work. How they will stand the wear and tear of every day working remains to be seen; but certainly the trolley takes the points so smoothly that it appears as if no difficulty of a serious character need be feared in practice.

The most interesting feature of the system is, of course, the side trolley, the details of which are shown in Fig. 4. The mast on the top of the car is just out of reach of the passengers. It is a hollow steel post, and the cable to the motor passes through

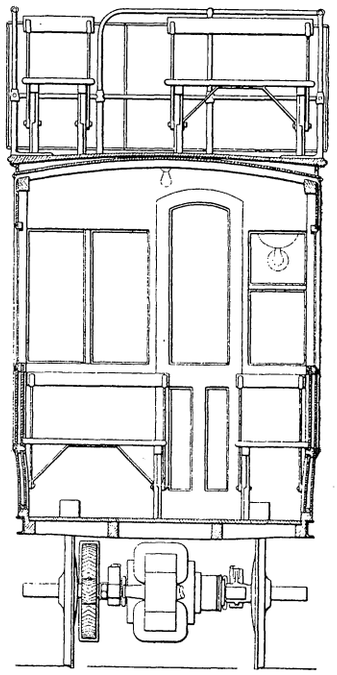

FIG. 3.—Sectional End Elevation of Car.

its centre. The pole obviously requires two motions, each of which must be automatically directed as quickly as the movement of the car may require it. In the first place there must be an upward thrust on the wheel, so as to press it firmly against the trolley-wire. This is managed by six strong cylindrical springs in tension acting on a tail bar. But in addition, a radial motion is required, to compensate the distance between the wire and the car, which varies from 13 to only a few feet. This is accomplished by allowing the trolley-pole to radiate freely about the centre of the mast on which it is mounted. The wheel is also swivelled at its point of support, and so keeps parallel to the line as the pole swings. The deep flanges of the trolley-wheel, and the upward thrust of the six springs, give the necessary directive motion to the pole. The arrangement is very simple, and works admirably, no doubt to the surprise of the many engineers, who said the side trolley was impossible in practice. Fig. 5 shows the bonding and fishing of the rails.

The power station has been designed by Mr. Dickinson with due appreciation of the necessities of the work. It presents a handsome exterior, in red brick with stone facings. At the back of the plot of ground is a canal, and a basin has been built alongside the coal-bunkers, so that barges can be cheaply unloaded. The three boilers, which are near the bunkers, are of the Lancashire type, with Galloway tubes, and are fitted with the usual injectors and steam pumps. The boiler shed is separated from the engines and dynamos by a brick wall. There are three engines and the same number of dynamos. The former, by Musgrave, of Bolton, are compound-condensing engines, with Corliss valve gear, and are each coupled to a dynamo by ropes. The dynamos are shunt-wound with drum armatures, each giving 350 volts and 275 amperes at 450 revolutions per minute. They are of the usual Elwell-Parker, two-pole single magnetic circuit type, with three bearings. It is proposed to run about 14 cars at first, so

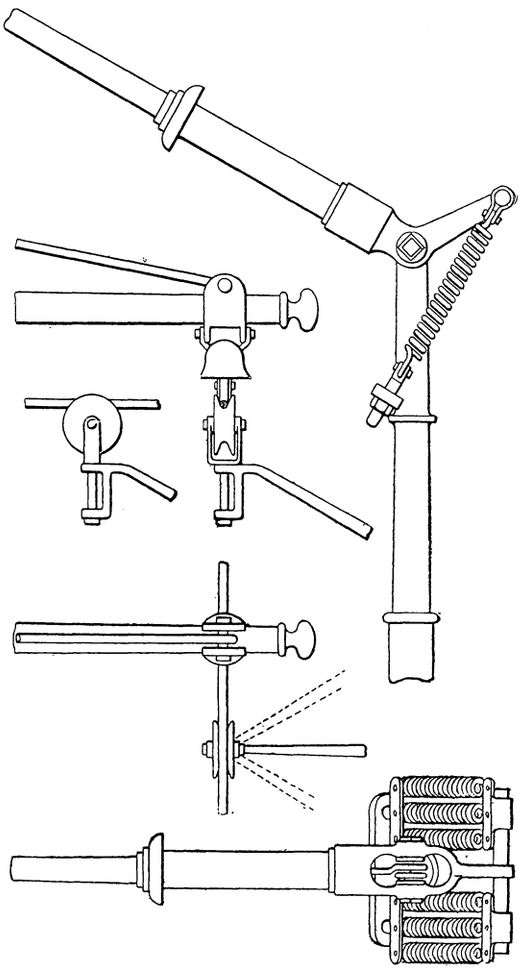

FIG. 4.—Plan and Elevation of Joint in Trolley Rod, showing Springs and details of end of Bracket and Wire.

that two dynamos will be amply sufficient to cope with the work, and the third will be in reserve. The dynamo-room is sufficiently large to allow for additional plant should the traffic require it at a future date.

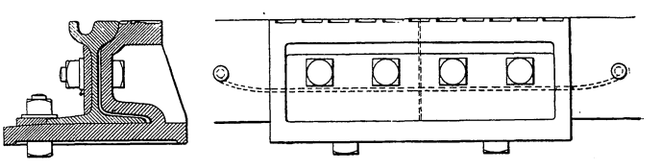

FIG. 5.—Joint in Rails. Combined Fish Chair and Sole Plate and Bonding Wire.

The whole of the work has been carried out by the Electric Construction Corporation, to the specification of Mr. Dickinson, Mr. Ted Parker acting as resident engineer on behalf of the Wolverhampton firm. We are pleased to see electric traction so energetically and ably carried out by a British firm, and hope that the South Staffordshire Street Railway will prove to be the forerunner of a number of similar installations. Our engineers evidently do not need the assistance of Americans to show them how traction work should be done; they only lack opportunity.

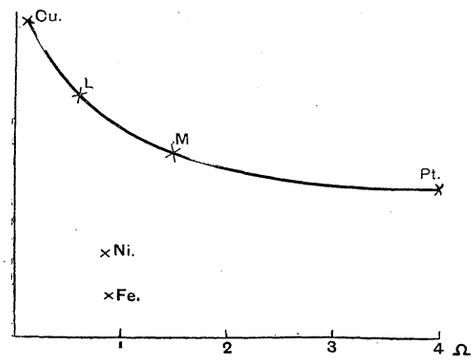
The official inspection of the plant was made on Saturday last by Major-General Hutchinson and Major Cardew. The inspecting officers reached James Bridge soon after half-past twelve, and were met there by the Mayor of Walsall, the Town Clerk and the Borough Surveyor; the Mayor of Wednesbury, the Town Clerk and the Borough Surveyor; Messrs. C. James, C. E. Davison and F. H. Lloyd (Directors of the Company); Mr. A. Dickinson, General Manager; Mr. T. Parker, of the Electrical Construction Company; M. Max Johannet, of Paris. The party mounted one of the new cars which was in waiting, and proceeded to the depôt at Darlaston, where the motors were inspected. Thence a run was made back to the generating station, and, after the appliances there had been passed in review, the line itself was gone over. The passage of the car attracted crowds of spectators at various points, and the inspection extended over $3\frac{1}{2}$ hours. The several steep gradients on the route, and the curves and junctions were all passed smoothly, and there was not a hitch from beginning to end. The date for the beginning of traffic under the new system will be definitely fixed when the sanction of the Board of Trade has been received.

ON THE DISSIPATION OF THE ELECTRICAL ENERGY OF THE HERTZ RESONATOR.*

BY V. BJERKNES.

In introducing conducting wires on different metals into his resonator Hertz asserted that neither the resistance nor the magnetic properties of the metal involved a sensible change in the length of the secondary spark.† We should, therefore, be tempted to conclude that the oscillations are completely independent of the nature of the metal. This independence is, however, only apparent. In my researches I employed a circular resonator having a diameter of 0·40m., and a complete period (double) of 14×10^{-8} second. The poles took the shape of vertical parallel discs 0·008m. apart, and 0·03m. in diameter. In the field constituted by the gap between these discs a piece of aluminium foil, forming an angle of 45deg. with the azimuth of the discs, was suspended by a quartz thread as an electrometer needle. Instead of the secondary spark the deflection of this needle was observed.

In this resonator I employed in succession geometrically identical conducting wires of different metals, and I obtained very different deflections. In the annexed diagram I give the



results obtained with six wires, all of 0·5mm. diameter, but made of copper (Cu), brass (L), nickel (Ni), iron (Fe), German silver (M), and platinum (Pt) respectively. The resistances of the wires are marked as abscissæ, and the ordinates show the deflections of the electrometer needle.

The results given in this figure appear at first glance singularly opposed to those obtained by Hertz. I think, however, that this divergence is only due to the difference of the methods. The oscillations of the resonator commence at zero and rapidly tend to a maximum, and gradually decrease afterwards. By the spark we evidently measure the height of this maximum; by the electrometer we measure the sum of all the oscillations. Owing to damping, this sum may have very different values without materially altering the height of the maximum. Consequently, the observations of Hertz show that the resonator always receives the same amount of electrical energy; the electro-magnetic measurements show that this energy is dissipated more or less quickly, according to the nature of the metal.

The capital point is thus the dissipation. The laws which govern it are represented indirectly by the diagram; a small ordinate corresponding to a rapid dissipation. It will be seen that the four non-magnetic metals ranged themselves on a curve having uniformly decreasing ordinates. On the other hand, the two magnetic metals, that is to say iron and nickel, are quite outside the curve, and the most magnetic metal is that which is the furthest from the curve. I have, therefore, come to the following conclusion:—*The rapidity with which the electrical energy of the resonator is dissipated is increased by the resistance and the magnetism of the conducting wire.* This dissipation may take place in two different ways, by radiation across the dielectric medium or by transformation into heat in the conducting wire. The considerable influence possessed by the physical constants of the metals seems to indicate that the transformation into heat is the principal cause. This transformation takes place in the thin superficial layer along which the electric currents flow. I endeavoured to determine the thickness of this layer with a view of getting to the bottom of the question.

To ascertain this, I covered the iron wire with thicker and thicker electrolytic layers of copper, and I found that the deflections of the electrometer increased, approaching asymptotically to the value of the deflections which took place in the case of the solid copper wire; the difference between the wires disappeared when the layer had a thickness of 0·01mm. I next covered the copper wire with electrolytic layers of iron; even a layer 0·0002mm. thick had an appreciable effect. The deflections very quickly approached the value which they had in the case of the solid iron wire, and all difference disappeared at the moment when the layer exceeded 0·003mm. in thickness. *I conclude, therefore, that the currents penetrate less deeply into the magnetic metals than into the non-magnetic metals.*

This result explains the part played by magnetism in the dissipation of electrical energy. The currents being confined to a thin layer, these would encounter a greater resistance, and consequently there would be a greater generation of heat. This explanation agrees with the theory already put forward by Lord Rayleigh and Herr Stefan. I may remark in conclusion that the penetration of alternating currents into the metals is a phenomenon of the same nature as the penetration of light into them. The results which I have obtained are sufficient to prove that metals are more transparent to luminous undulations, which agrees perfectly with theory.

THE PROBLEMS OF COMMERCIAL ELECTROLYSIS.

The following is an abstract of the Discussion of Mr. Swinburne's Paper on "The Problems of Commercial Electrolysis" which took place on Thursday last week at the Institution of Electrical Engineers. Speakers whose remarks are prefixed by an asterisk have returned their abstract revised. Mr. Swinburne's Paper appeared in *The Electrician* of August 5th and 12th.

Mr. C. F. COOPER said that he had been for some years connected with the Hermite process, and would give a short description of the way in which this is worked. On the Continent this was a going concern and a great success. There was a little châlet in the grounds of the Antwerp Exhibition in which an electrolytic process of bleaching was carried on. Mr. Hermite at that time was bleaching linen yarns. Diagrams were exhibited showing the arrangement of the plant in its present form. The electrolyser consists of a galvanised cast-iron box, and of a certain number of electrodes. They experimented with everything that could be imagined in the endeavour to get an unattackable anode, and fell back at last on platinum. Of course it was necessary to reduce the weight of platinum as much as possible for commercial reasons, and they originally started with very thin foil. The foil had many disadvantages; it had a knack of expanding and short-circuiting, and generally behaving like the secondary battery of old days. Eventually a platinum gauze anode was used. Prac-

Hosted by Google

tically the results were the same with the same weight of platinum as if a solid sheet had been employed. These gauzes were mounted in ebonite frames. In practice there is practically no attack on the platinum anode. The process has been in use for six years and out of ten electrolysers they had certainly not put in one new set of anodes. The Hermite process was based on the decomposition of magnesium chloride. The process was essentially a continuous one. A solution of magnesium chloride in the top tank ran down to the bottom tank. They used a thousand amperes at five volts. They occasionally ran them as many as eight in series, but preferred five in practice. The decomposition took place in the second tank, and ran down into the poacher. It was washed in the ordinary washing drum used in a paper mill. When the pulp was bleached of course there was a certain amount of solution left in the pulp. This was treated and got back again, because one of the principal points in the Hermite process was that they used the same solution over and over again. It was run down from the poacher either into a drainer or over a press-plate. A press-plate took out, say, about 40 per cent. of moisture, and it was necessary to pass the pulp over a press-plate in the first instance, and then, after bleaching, to pass it over another press-plate. In dealing with carbon, he used various sorts years ago, and always found that it disintegrated on the water line, and they got small specks of black in their pulp ; instead of a bleaching solution they had practically a dyeing solution. They had the same difficulty in dealing with the pipes and conduits which conveyed the solution from one part of the mill to the other. They thus dyed many tons of pulp a beautiful green. That was due to the copper in the washing ground. They had to take all the copper away and put in zinc. They used occasionally to dye a very nice rich red, from the fact of peroxide of iron being present.

* Mr. C. K. FALKENSTEIN said that Mr. Swinburne stated, in the reference which he made to electric tanning, "If the skin is merely left in the tan liquor, it takes months for the liquor to penetrate even into the interstices." From this it would appear that the structure of the hide and the pores or interstices between the fibres were very close and narrow indeed. But in the preparatory process of liming, the cement-substance which joined the fibres together was dissolved away by means of the lime, which also "plumped" or swelled up the hide and separated the fibres, leaving it fairly porous, for the diffusion and absorption of the tan liquor. When the hide went into the tan, the tannage at first progressed very rapidly, for this reason, viz., that the pores were filled with water and organic salts, which diffused out very rapidly, thus creating a partial vacuum which tended to draw the tan liquor in. The rate of absorption, however, gradually grew slower and slower as the amount of these bodies present in the hide became less and less, since tannin, being a colloid body, had a very slow rate of diffusion by itself. If, now, a current of electricity were passed through the hides, it impelled the tan liquor in the same direction as the lines of current flow, a greater quantity of tannic acid solution being thus brought into contact with the gelatinous fibres of the hide. In tannic acid solution, endosmose effects were fairly powerful, this being due, perhaps, to the molecular structure of tannic acid ; and from the fact that it had a high resistance, comparatively high differences of potential could be employed to produce this endosmotic flow without necessitating the use of a large current and therefore a large expenditure of energy in the process. The fact observed by Messrs. Rideal and Trotter last year in their work on this subject, viz., that the increased rate of absorption was maintained for some time after the current was stopped, was due, no doubt, to the pores having been cleansed and opened by the endosmotic flow of liquor through them. The above accounted for increased diffusion, but there was another effect which may be noticed, viz., that electricity was of the nature of a vibration, and thereby tended to accelerate or assist the combination of the tannic acid with the gelatinous fibres. Mechanical agitation, too, was commented upon in the Paper, and had, he thought, two functions, viz.—1st. To mix the liquor and render it of uniform strength. 2nd. To bend the hide and open the pores on the outer side of the bend, thereby also assisting diffusion.

Mr. STEPNEY RAWSON said that Mr. Swinburne put the cost of the kilowatt hour at about a farthing, and said it would appear ridiculous in connection with central stations. Unless he had some figures arising out of his visit to Bridgeport to confirm the farthing per hour, it would appear not ridiculous but very small to those who are engaged in commercial electrolysis ; but at the same time he did mention the best engines and modern dynamos. They knew pretty nearly what the modern dynamo is capable of, but they did not quite know what the modern engine was capable of. An exceedingly good authority told him that, in a succession of tests he had made on the commercial working, the efficiency ran anywhere between 28lb. and about 4lb., so that there was a certain margin ! People were very fond of putting down on paper 2¼lb., and in France a kilo corresponds so nearly with that that they always called it a kilo, but it was almost impossible to get it in practice. In actual working one of the greatest enemies is leakage. Theoretically, it was easy to get rid of it. There were a thousand ways in which leakage took place which would surprise even an old hand ; moreover, a large number of parasitical currents were set up, and they might hunt round for weeks before they find out where they arose. Therefore, although at the dynamo terminals they might arrive at a farthing, he thought by the time the current had, so to speak, got back again, they would find it took a great deal more. With regard to the carbon that, no doubt, is a source of difficulty, and many people have had trouble with it. With a very heavy current density, that was a current density of 100, carbon behaved tolerably well. When he got down to ten, it disintegrated very much faster. Regarding the treeing of zinc and lead, the arrangement of burnisher which the Elmores used, has proved very successful in removing that difficulty. He had seen a solution of zinc deposited with a sulphate solution with a porous partition come out very definitely indeed. In the same way the treeing of lead could be fairly easily kept down.

Mr. C. F. CROSS was interested in the Hermite process when it was first brought to this country in 1884-5, and of course viewed it with the amount of scepticism which, specialist as he was at that time in matters of bleaching, and knowing nothing of electrolysis, he was entitled to feel. A somewhat acute controversy on the subject took place in 1887-8, and was recorded in the *Journal* of the Society of Chemical Industry. So long as electrolysis had been confined to the actual separation of bodies in a condition to be weighed, there could be no doubt, of course, as to the efficiency of the current, and no doubt either as to the measurement of the current in the terms of the product obtained. But when they had to get that product to do work in a transitional state, and having done work to revert to something like the *status in quo* there came, of course, an element of doubt and difficulty. They had to catch a particular element, namely, oxygen, flying, and that led to some very remarkable results. They had found that in bleaching powder units, the work of a ton of bleaching powder could be effected on the electrolytic plan at a cost of from £2. 10s. to £4. That is to say, given a certain amount of bleaching work to do, and requiring a certain amount of bleaching powder to do it to the weight of one ton, and costing, of course, from £7 to £8 at then rates, it could be done at from £2. 10s. to £4. They found always from 70 to 90 per cent. of the current efficiency, and the compound produced clearly was not the ordinary chlorine. They showed that there was formed at the cathode an active oxidising compound, and this stirred into the solution was dissolved, and no doubt contributed largely to the particular efficiency of the solution. In these experimeuts they carefully compared bleaching powder in the ordinary chemical process, and the electrolysis in Hermite's method, and they found that 26 per cent. of the bleaching powder was used in the chlorination effect ; 14 per cent. of the total used, went into this by-path or in some other direction, but with the electrolysed solution prepared by Hermite there was no chlorination at all.

Prof. PERRY suggested that for a society of that kind they should have actual figures of the cost, as compared with the cost of bleaching powder, not speculative figures, such as appeared in the papers five or six years ago. He would also suggest that Mr. Swinburne should put, as an addition to his Paper, the materials from which he had produced this farthing per unit.

Mr. DESMOND G. FITZGERALD said that every sample of peroxide of lead he had tried contained a considerable proportion of sulphate. In that case acid would be produced at the anode, and the sulphuric acid reacting on the sodium chloride would, of course, produce hydrochloric acid ; but in practice it was the easiest thing possible to maintain the solution at the anode in the alkaline condition to any required extent. There need never be any free acid where chlorine is being evolved ; but supposing that hydrochloric acid were evolved, peroxide of lead in the form of lithanode was perfectly indifferent to the action of hydrochloric acid, so long as the current was continued. If peroxide of lead or a plate of lithanode was placed in hydrochloric, they would obtain chloride of lead and chlorine would be evolved ; but if the peroxide was made the anode, chlorine would be evolved, but no chloride of lead would be produced. He handed round a plate, which he took out of a solution of hydrochloric acid, in which it had been used as anode, and producing chlorine for eight or ten hours. The plate was not affected, and that would also have been the case if it had been left two or three days, or two or three weeks. Anyone interested in the matter could examine that. Mr. Falconer, the only person capable of speaking from actual experience of the use of lithanode as an anode employed on a large scale, had sent some old anodes of lithanode and peroxide of lead, which had been used in a solution of chloride magnesium, and which had been exposed to the solution for a long time. The plates were covered with a white substance, which suggested chloride of lead, but it was magnesium hydrate ; the peroxide underneath was perfectly intact. A thing which was quite fatal to the use of magnesium chloride as a supplier of chlorine, was the fact that at ordinary temperature magnesium hypochlorite had a strong tendency to become converted into chlorate. He could speak with a little authority on this point, because after a certain experiment, to which Prof. Perry and Prof. Meldola were called in, they were all very much surprised to find that there did not seem to be any relation between the quantity of current expended and the quantity of chlorine produced. After these unsatisfactory results in conjunction with his assistant, Mr. Burman, they compared the quantity of current expended and the quantity of chlorine produced. After a certain strength had been obtained, there seemed in some instances to be an actual disappearance of chlorine by the passage of the current, and the solution of the mystery ultimately turned out to be that chlorates were produced at ordinary temperatures in considerable abundance. As instances of the many small operations in which electrolysis might probably be advantageously introduced, he suggested the conversion of arsenious acid into arsenic acid ; the conversion of ferrous prussiate of potash into the ferric, or the yellow prussiate into the red ; and again the purification of acids, sulphuric acid and hydrochloric acid on a large scale, the separation of lead from sulphuric acid and iron and zinc from hydrochloric acid.

* Mr. A. E. MAVOR alluded to Mr. Swinburne's remark : "The first manufacturers to take up copper refining by electrolysis on really modern principles have a chance of making fortunes before the market is disturbed." Now this would really have been a most momentous sentence were it not for the fact that some manufacturers had already taken the matter up, and were making fortunes. Some of the oldest copper manufacturers in the country had taken it up with great enthusiasm and energy, precisely on the principles Mr. Swinburne described, and he did not think there was any danger that that particular branch of the electrical industry was the least likely to fall asleep.

Mr. A. C. FALCONER had carried out certain experiments, extending over close upon four years, and lithanode anodes that he had brought to the meeting had been in solution at least three years, and had not been injured in any way whatever. He did not replace one single plate, except

Hosted by Google

when they were broken, but all the others were in solution for about two years. His experience extending over four years was that lithanode was indestructible in solution, and he believed that Mr. Fitzgerald's theory was perfectly correct, that they could even decompose hydrochloric acid by lithanode without injury.

Mr. SWINBURNE asked Mr. FALCONER whether there was oxide of magnesia on the lithanode.

Mr. FALCONER replied that Mr. Fitzgerald thought it would be better to have the anodes at the bottom of the bath with plenty of magnesia on them. He was surprised to hear Mr. Cooper defend so strongly the use of platinum. He could tell them that platinum was attacked by chlorine. It must give way sooner or later.

Mr. SWINBURNE asked whether the lithanode stood perfectly untouched when it was vertical without any magnesia on it.

Mr. FALCONER pointed to a specimen of the anode of the vertical pattern on the table. They connected up the lithanode in the ordinary way with platinum connections. They found if there was the merest pinhole in the insulation the platinum would disconnect itself from the anode.

* Dr. S. P. THOMPSON desired to direct the discussion towards some points, perhaps, of more general interest than the detail of a single process, however important that process may be in itself. He questioned whether details of processes were much worth discussing unless they had the commercial basis, namely, the figures. He would like to point out that when one comes to put any one of these processes on to a commercial basis one is bound to meet with difficulties that cannot be anticipated from the laboratory, and which seriously interfere with the question of possible profit in working. He described the failure of the Hermite processes in a paper mill where, though the bleach liquor was satisfactorily made, the pulp was bleached and dyed at the same time, with the consequence that the dilute liquor coming into the vat brought a large quantity of water with it. It was not that the bleach liquor was defective, but their way of using bleach liquor made the process one that did not pay. Mr. Swinburne had not touched on one or two processes which he believed were used commercially. He did not mention the process of galvanising iron by the aid of a skin deposit of zinc, first of all deposited electrically, before the sheets are dipped into molten zinc. Then, again, Mr. Swinburne did not do him the honour of mentioning a process of depositing cobalt, he supposed for the very good reason that it did not come under the head of *commercial* electrolysis. He wished it did. He found from experience that the one white metal which would stand a London atmosphere, fog, and the products of combustion, was the metal cobalt. In text-books on such subjects figures are given for electro-chemical equivalents of metals in their different states, of ferrous iron for example and for ferric iron. He was not at all sure whether those distinctions were not absolutely absurd ; at any rate they were so in the case of ferric salts. They were not able to get a deposit of iron from ferric salts. Before they could obtain a deposit from ferric salt it had to be reduced to the ferrous state, and they only got a deposit from ferrous iron and not truly from ferric iron. Another point which ought to be borne in mind was the necessary minimum electromotive force to produce any action whatever of a chemical nature. Probably it might make the whole difference between its being commercially valuable and commercially valueless that they should know that minimum electromotive force in each case. He would say a word about processes, such as that of Hermite, which were cyclic processes where the material went round and round and was regenerated after being used. The difference between a non-cyclic process and a cyclic process made all the difference in the world between success and failure. He believed Dr. Hurter's mistakes arose very largely from his not recognising the difference between a cyclic process and a non-cyclic one. A cyclic process would pay where a non-cyclic process possibly could not. He further remarked that as in electric tanning, in which electrolysis played so small a part and electric osmose played so important a part, so he believed there were other cases in which osmose is the important part. For example, it was quite possible to separate to a certain extent animal and vegetable oils from mineral oils by subjecting them to a species of electric osmosis.

PHYSICAL SOCIETY.

At a meeting of the Physical Society on October 28, 1892, Dr. J. H. Gladstone, F.R.S., past-president, in the Chair, the discussion on Mr. Williams's Paper

"On the Relation of the Dimensions of Physical Quantities to Directions in Space"

was opened by Prof. PERRY reading a communication from Prof. Fitzgerald, President.

The writer said Mr. Williams disagreed with the suggestion that electric and magnetic inductive capacity are quantities of the same kind, principally because he had not got over the curious prejudice that potential and kinetic energy are different. No theory of the ether could be complete unless it reduced its energy to the kinetic form. Electric and magnetic inductive capacity would probably be found to be similar in the ether, and ultimately have the same dimensions. The analogues were not yet complete, but only in respect of *matter* was it probable that any difference existed between them. Diamagnetism corresponded to electrostatic induction, but paramagnetism had no definite electrical analogue. He was inclined to regard the phenomena of paramagnetism as connected with the arrangement of the material molecules, whilst diamagnetism depended on the electric charges on those molecules. So far no matter had been found which conducts magnetism, and such may not exist in our universe, but it may be gravitationally repelled by matter as we know it.

Mr. W. M. MADDEN remarked that in the first part of his paper Mr. Williams recognised that dimensional formulæ were originally change-ratios, but puts this aside for the higher conception which regards these formulæ as expressing the nature of the quantity. Fourier showed how to find the dimensions of units by making the size of the fundamental units vary. But k (specific inductive capacity) did not vary with the fundamental units, for it was merely the ratio of the capacities of two condensers, and, therefore, by Mr. Williams's definition, a pure number. It was difficult, he said, to see how k could have dimensions, but Mr. Williams regarded it as a physical quantity, and, therefore, possessing dimensions. The object in giving dimensions to k and u seemed to be to get over the double system of units. That Mr. Madden did not think that the suppressed dimensions of μ and k were not generally accepted was shown by Dr. J. Hopkinson's insistance, at the last B.A. Meeting, that the coefficient of self-induction was a length, which Prof. Rücker said was inconsistent with belief in the physical dimensions of μ and k. Nor were these suppressed dimensions necessary to reconcile the two systems. The connecting link between them was the formula $Q = Ct$, which expresses a theory of the nature of an electric current admittedly inadequate to explain the facts, and recently much called in question. That the dimensions did not express the physical nature of the quantities might be seen from considering the astronomical unit of mass whose dimensions were $[L^3 T^{-2}]$. No one could contend that this formula indicated "how our conception of the physical nature of matter is formed." Mr. Madden argued that the obvious interpretation of this dimensional formula, and the way it was obtained, indicated the meaning of all such formulæ, and showed that they are the result of a convention that certain definitions should hold true generally, but they contain no further information respecting the nature of the quantities, beyond that involved in those definitions. As an example of the inability of such formulæ to express the nature of quantities, he pointed out that whilst physical differences were known to exist between + and − electricity, the dimensional formulæ showed no signs of such differences.

Prof. RÜCKER said every correct physical equation consisted of a numerical relation between physical quantities of the same kind, and might be written either as a mere numerical equation or as a relation between the physical quantities themselves. The equation $2 + 1 = 3$ may correspond to $2\text{ft.} + 1\text{ft.} = 3\text{ft.}$, and the latter may be writen

$$2[\mathrm{L}] + 1[\mathrm{L}] = 3[\mathrm{L}],$$

where [L] represents the unit of length. So far as he was aware nobody but a recent writer in *The Electrician* had denied that in such an equation [L] represented a concrete quantity, Maxwell explicitly stated that it does in his article on "Dimensions" (Encyl. Britt.) and elsewhere, and Prof. J. Thomson, in his Paper on the same subject, makes no statement contrary to this. The above equation might also be written

$$2[\text{ft.}] + 1[\text{ft.}] = 1[\text{yd.}]$$

Another equation involving time is

$$60[\text{sec.}] = 1[1\text{ min}],$$

and dividing one by the other, one gets

$$\frac{2}{60}\left[\frac{\text{foot}}{\text{sec.}}\right] + \frac{1}{60}\left[\frac{\text{foot}}{\text{sec.}}\right] = 1\left[\frac{\text{yard}}{\text{min.}}\right]$$

A difficulty was felt here in understanding what dividing a foot by a second meant, bnt this difficulty, Professor Rücker considered, was not greater than that involved in dividing an impossible by a real quantity ; a very familiar analytical device. Reasons for regarding the symbol

$$\left[\frac{\text{foot}}{\text{sec.}}\right]$$

as legitimate were then given.

Prof. HENRICI said the communication under discussion was one of the most important contributions to physical science which he had come across for a long time. Such difficulties as presented themselves in the Paper arose from its fundamental character. The author had attempted to express all physical quantities in terms of three, but quantities may exist which cannot be completely represented in terms of L, M, and T. The tendency of modern mathematics was to express everything dynamically. Mathematicians had long been in the habit of using quantities which were neither numbers nor concretes in the ordinary sense, and different kinds of algebra with units not understandable had been developed. If a quantity, a times a unit u, be multiplied by b times another unit v, the result is expressed by $a\,b$, $u\,v$, where $a\,b$ is a number and $u\,v$ a new unit, which may or may not be physically interpretable. The interpretation of a product depended on the meaning attached to "multiplication," and if this be restricted to "repeated addition" the range is very limited. The narrow conceptions concerning multiplication acquired at school could only be removed by a careful study of vectors. Mr. Williams had treated his subject by vector methods, but a few traces of quaternions remained which might be omitted. To truly understand the subject, vectors must be treated vectorially. Dimensions might then show the nature of the quantities involved. The system adopted in Mr. Williams's Paper was probably the best attainable at present, but he (Prof. Henrici) looked forward to the use of a more fundamental quantity than the vector, viz., "the point," as the ultimate basis. Grassmann had worked out a "point calculus" in 1844, which was republished in 1880. Quantities more complex than vectors, viz., rotors, screws, motors, &c., had been used with advantage by Clifford, Ball, and others.

Dr. SUMPNER thought the first ideas of students on the subject of dimensions were that they represented the nature of the quantities, but could not see why every quantity should be expressed in terms of L, M,

Hosted by Google

and T. Prof. Rücker's Paper on "Suppressed Dimensions" had cleared up several important points, and he (Dr. Sumpner) now considered that every quantity must be expressed in terms of a unit of the same kind as itself. He viewed Mr. Williams's attempt to express everything in terms of L, M, and T, as rather a retrograde step.

The discussion on Mr. Williams's Paper was adjourned, and Dr. Young made some remarks on Mr. Sutherland's communication, "On the Laws of Molecular Force." A Paper "On the Determination of the Critical Density," by Dr. Young and Mr. G. L. Thomas, B.Sc., and two Papers, "On the Determination of the Critical Volume," and "On the Boiling Points of Different Liquids at Equal Pressures," by Dr. Young, were taken as read.

On Nov. 11th the discussion on Mr. Williams' Paper, "The Dimensions of Physical Quantities" was resumed by Dr. BURTON.

He remarked that the idea that so-called "specific quantities," such as specific gravity are pure numbers, was an erroneous one, and liable to lead to difficulties. The specific gravity of a substance was of the nature of density, and was only a simple number on the convention that the density of water was taken as unity. If dimensions be given to specific quantities, their interpretation would, he thought, be easy when the rational dimensional formulæ were found. Referring to Prof. Fitzgerald's comments, he said, although the contention that all energy is ultimately kinetic, could not be gainsaid, the distinction commonly drawn between kinetic and potential energy involved nothing contrary to this view, and was useful and convenient in many cases. As to the dimensions of μ and k he was inclined to favour Mr. Williams' views, for several considerations suggest that the two capacities of the medium are essentially different. Arguments to show that μ was probably absolutely constant in the ether, whilst k might be variable were brought forward. Of the two systems of dimensions for μ and k suggested by Mr. Williams, that which made μ a density seemed preferable.

Prof. A. LODGE said he was greatly interested in propagating the idea that physical quantities are concrete, and therefore welcomed Mr. Williams' Paper. He thought it desirable to keep some names for abstract numbers, and "specific gravity" should be one. If another name involving dimensions was required, "specific weight" or "weight per unit volume" might be used. Speaking of the dimensions of the various terms of an equation, he did not think it was usually recognised that in ordinary algebra or Cartesian geometry the principle of directed terms was rigidly adhered to, for, if directed at all, every term of such an equation was directed along the same line. In this respect ordinary algebra was more rigid than vector algebra. Even if circular functions were involved, as in polar co-ordinates, they had the effect of making the directions of the terms the same. Other instances of problems bringing out the same fact were mentioned.

Prof. V. BOYS thought Mr. Madden had been arguing in a circle when he spoke of the astronomical unit of mass, and deduced the dimensions of mass as L^3/T^2 from the equation $M L T^{-2} = M^2/L^2$, for it was quite impossible that this equation could be true, unless γ the gravitation constant was introduced on the right-hand side. Mr. Williams' method was quite the reverse, for he maintained that unless k and μ were introduced in the dimensions of electric and magnetic quantities, their dimensional formulæ could not indicate the true nature of those quantities, and hence were open to objection.

Mr. W. BAILY, whilst agreeing with Mr. Williams on most essential points, thought the total omission of L from dimensional formulæ made the expressions more complicated and less symmetrical. For example, such expressions as $X Y/Z$, X^2, and $X Y Z$, which respectively represent undirected length, area, and volume, might with advantage be written L, L^2, and L^3 respectively. The restriction of the dimensions of μ and k to those which give interpretable dimensional formulæ for electrical and magnetic quantities seemed scarcely justified. Both the systems proposed could not be right, and he thought it would be more in accordance with our present want of knowledge if a quantity U of unknown dimentions were introduced such that μ or $k = U^2$ density, and k^{-1} or $\mu^{-1} U^2$ rigidity. This would keep in view the fact that the absolute dimensions of quantities involving U were unknown. A list of the dimensions of the various quantities based on this arrangement was given.

Mr. SWINBURNE, referring to the conventional nature of many units, said great differences exist between the ideas held by different persons about such units. Starting with the convention that unlike quantities could be multiplied together, he might have six amperes flowing in an electric circuit under a pressure of 10 volts, and he might say he had 60-volt amperes. The term "volt ampere" could be regarded as indicating that the 60 was the numerical result of multiplying a number of volts by a number of amperes, or, on the other hand, it might be understood as a new unit, a *watt* compounded of a volt and an ampere. Before Prof. Rücker's Paper on "Suppressed Dimensions" was published, an electrician might have suggested measuring the length of a bench by sending an alternating current through it, and determining its self-induction, which he regarded as a length. Prof. Rücker, however, would say that this could not give the right result, for μ must be taken into account. He was inclined to think that dimensions were liable to mislead. Referring to scientific writers as authorities, he said Maxwell had been careless in some cases, for he had sometimes given dimensional formulæ as zero, which really ought to have been $L^\circ M^\circ T^\circ$, or unity. In French text-books the errors had been corrected.

Mr. WILLIAMS, in reply to Mr. Madden's remarks about self-induction being a length, pointed out that the subject might be looked at in two different ways, depending on whether one thinks of the *standard* of self-induction as the practical standard of measurement, or the *unit* of self-induction as a physical quantity. In the former case the *standard* was a length; but in the latter the *unit* was a quantity of the same *species* as self-induction, the nature of which was, as yet, unknown. If its dynamical nature was known, then the absolute dimensions of all other magnetic and electric quantities would also be determined. In answer to Prof. Fitzgerald's remarks he said it was hardly likely that he should be unacquainted with the common view that kinetic and potential energies were ultimately quantities of the same kind, for it was a view with which he was quite familiar. The fact that they have the same dimensions was sufficient to show their identity, and the idea that all energy is ultimately kinetic was fundamental to his Paper. This, however, did not imply that electrification and magnetisation are of necessity the same, and the suggestion that they may be the same was only one of several "probable suggestions," all of which were entitled to consideration. His chief reason for regarding Prof. Fitzgerald's suggestion as probably incorrect was that it led to a system of dimensional formulæ incapable of rational mechanical interpretation, and containing fractional powers of the fundamental units. Prof. Fitzgerald's system would make resistance an abstract number, and μ and k directed quantities, whereas the former was a concrete quantity, the two latter must be scalar in isotropic media. If he (Mr. Williams) had erred in treating electrification and magnetisation as different phenomena, he could only plead that he had done nothing more than follow such authorities as Lord Kelvin, Dr. Lodge, and Mr. O. Heaviside in the matter.

COMPARISON OF THE FRICTION OF COTTON MILL ENGINES AND GEARING TO THE ACTUAL WORK DONE.*

BY ALFRED SAXON.

In bringing this subject before your notice I feel it is one that is deserving of our attention, and I trust it will be the means of enabling us to do something to prevent the loss of power and economy which exist in engines and gearing at the present time from this cause. Thurston says, "Friction is a resistance which is always met when two bodies or particles, whether solid, liquid or gaseous, are compelled to move, one upon another. There are three kinds of friction, so called; rolling and sliding with solids, and fluid friction with liquids and gases. These are all governed by different laws, and with each the statement of those laws as usually given in the text-books probably require some modification." It is not my intention to attempt to analyse the different kinds of friction created in engines and gearing; I shall deal with all kinds of friction under the general head of friction. It will also be impossible for me to furnish minor details of such engine and gearing arrangements that I shall refer to, as time and space will be occupied in a general description. I have not been successful in obtaining permission to indicate some of the engines I had intended, and in one or two cases of refusal, perhaps, the least said the better. You will no doubt agree with me that running large engines up to their ordinary working speed without weight on is not a very desirable thing, and is occasionally productive of hot bearings, which I believe is the true explanation of consent being withheld in some instances.

In the examples I shall refer to I have not attempted to select very extreme cases, such as I know do exist, but I have tried to select examples which will fairly illustrate mill engines and gearing which have been constructed within a comparatively recent date. Economies are being effected in steam engines at the present time by utilising higher pressures of steam, but we shall not be long in reaching a safe working limit in that direction.

There is no doubt that along with this increase of pressures, we have had an increase of speeds in engines and gearing. We, as an industrial people, are drawing rapidly upon the coal supply, and if we must leave coal for the use of the generations yet unborn, and at the same time cheapen the cost of our productions, we must, in our different positions as practical engineers, consulting engineers and mill architects, in drawing up specifications and carrying them out, use every available means of improving the efficiency of the engines and gearing of our manufactories. There are a variety of ways of judging of the economy of steam engines and gearing, the commonest being the number of pounds of coal per indicated horse power per hour, another test being that of the weight of steam used; these, however, are only partial tests. The test which many mill owners apply in a rough and ready sort of way, that of reckoning the number of spindles of either twist or weft, or both, and the counts of the yarn and the weight spun for a given quantity or value of coal, in comparison to their neighbours who have similar mills, is a good proof of economical working, if taken into consideration with the tests above mentioned.

In the term "Actual work," in the examples given, I wish it to be understood that I include all the power absorbed in driving the machinery, after deducting the friction of the engines and gearing from the total load. That is, treating the friction in the machinery itself and the work done by the machinery as "Actual

* Abstract of a Paper read before the Manchester Association of Engineers.

Hosted by Google

work." If the coal consumption were based on the actual work done it would give some startling results, as is shown by a study of the following examples :—

Spur Gearing Engines.

1st Example.—Pair of horizontal compound tandem engines with high-pressure cylinders 24in. diameter, low pressure cylinders 48in. diameter, all 5ft. 6in. stroke, making 51 revolutions per minute, or a piston speed of 561ft. per minute. Fly spur driving wheel 14ft. 6½in. diameter, 5in. pitch, 18½in. broad, pinion 6ft. 7in. diameter. Indication with full load, and boiler pressure of 110lb. work out to 1309·6 I.H.P. Indication of friction with the whole of the gearing and engines at work equals 385·76 I.H.P., being 29·47 per cent. of the total load, leaving an actual load of 70·53 per cent. on the engines. Description of gearing : Wheel and rope driving, partly new and partly old, not supplied by engine maker.

2nd Example.—Pair of horizontal compound tandem engines with high pressure cylinders 21in. diameter, low pressure cylinders 42in. diameter, all 6ft. stroke, making 35½ revolutions per minute, or a piston speed of 426ft. per minute. Fly spur driving wheel : Indication with full load and boiler pressure of 110lb. work out to 989·54 I.H.P. Indication of friction with the whole of the gearing and engine at work equals 217·49 I.H.P., being 22 per cent. of the total load, leaving an actual load of 78 per cent. on the engines. Description of gearing : Wheel and rope driving new, not supplied by engine maker.

3rd Example.—Pair of horizontal compound engines, with high-pressure cylinder 16in. diameter, low-pressure cylinder 28in. diameter, both 4ft. stroke, making 70 revolutions per minute, or a piston speed of 560ft. per minute. Fly spur wheel. Indication with full load, works out to 250 I.H.P. Indication of friction with the whole of the gearing and engines at work equals 87·62 I.H.P., being 33·2 per cent. of the total load, leaving an actual load of 67 per cent. for the engine. Description of gearing : Old.

P.S.—The friction at 64 revolutions per minute equals 73·17 I.H.P.

5th Examp'e —Pair of horizontal triple-expansion tandem (formerly compound, recently tripled) engines, with high-pressure cylinders 14½in. diameter, intermediate cylinders 23in. diameter, low-pressure cylinders 36½in. diameter, all 6ft. stroke, making 51 revolutions per minute, or a piston speed of 612ft. per minute. Fly spur driving wheel 14ft. 8⅝in. diameter, 4 1/16in. pitch, 18in. broad, 115 teeth ; pinion 6ft. 7⅛in. diameter, 52 teeth. Indication of full load with boiler pressure of 160lb. works out to 1,044·5 I.H.P. Indication of friction with the whole of the gearing and engines at work equals 205·95 I.H.P., being 19·7 per cent. of the total load. Description of gearing : Wheel gearing throughout.

8th Example.— Pair of compound McNaughted beam engines, high-pressure cylinders 35in. diameter, by 3ft. 6in. stroke, low-pressure cylinders 42¼in. diameter by 7ft. stroke, making 33 revolutions per minute, or a piston speed of 462ft. per minute for the low-pressure pistons. Fly spur wheel 25ft. diameter, 4½in. pitch, 16in. broad, 210 teeth, pinion 6ft. 1in. diameter, 51 teeth. Rim speed 2,590½ft. per minute. Indication of full load with a boiler pressure of 90lb. work out to 1,150 I.H.P. Indications of friction with the whole of gearing and engines at work equals 209 I.H.P., being 18·17 per cent. of the total load, leaving 81·83 per cent. of an actual load on the engine. Description of gearing : Wheel gearing throughout ; mule driving direct from line shafts.

9th Example.—Pair of triple expansion (formerly compound, recently tripled) engines with four cylinders. Indication of full load with boiler pressure of 160lb. works out to 1,145 I.H.P. Indication of friction with the whole of gearing and engines at work equals 300 I.H.P., being 26·2 per cent. of the total load, leaving an actual load of 73·8 per cent. on the engine. Description of gearing : Wheel gearing throughout.

10th Example.—Pair of compound McNaughted beam engines. Indication with full load at boiler pressure of 64lb. works out to 821·26 I.H.P. Indication of friction with the whole of gearing and engines at work equals 207·96 I.H.P., being 25·3 per cent. of the total load, leaving 74·7 per cent. of an actual load on the engine.

Rope Driving Engines.

1st Example.—Pair of horizontal compound side-by-side engines, high-pressure cylinder, 32in. diameter, low-pressure cylinder, 60in. diameter, both 7ft. stroke, making 52 revolutions per minute, or a piston speed of 728ft. per minute, Rope pulley 34ft. diameter, grooved for 32 ropes. Speed of ropes 5,554·3ft. per minute. Indications of full load with boiler pressure of 94lb. per square inch work out to 1,272 I.H.P. Indications of friction with the whole of the gearing and engines at work equals 296 I.H.P., giving 23·3 per cent. of friction. Friction at 50 revolutions equals 270·3 I.H.P. Gearing new, but not made by engine maker.

2nd Example.—Horizontal compound tandem engine, high-pressure cylinder 22in. diameter, low-pressure cylinder 44in. diameter, grooved for 28 ropes 1¾in. diameter, speed of ropes 4,838ft. per minute. Indications of full load with boiler pressure of 90lb. work out to 1,025 I.H.P. Indications of friction with the whole of gearing and engines at work equal 32·493 I.H.P., giving 31·7 per cent. of friction. Description of gearing : New, not supplied by engine maker.

5th Example.—Pair of horizontal compound tandem engines, with high-pressure cylinders 20in. diameter, low-pressure cylinders 40in. diameter, all 5ft. stroke, making 60⅓ revolutions per minute, or a piston speed of 603⅓ft. per minute. Rope pulley 28ft. diameter grooved for 26 ropes 1¾in. diameter, speed of ropes 5,306ft. per minute. Indications of full load with a boiler pressure of 90lb. works out to 978·25 I.H.P. Indications of friction with the whole of the gearing and engines at work equal 283 I.H.P., giving 28·9 per cent. of friction. Description of gearing : New, not supplied by engine maker.

6th Example.—Pair of horizontal compound tandem engines, with high-pressure cylinders 20in. diameter, low-pressure cylinders 40in. diameter, all 5ft. stroke, making 57 revolutions per minute, or a piston speed of 570ft. per minute. Rope pulley 28ft. diameter grooved for 24 ropes 1¾in. diameter. Speed of ropes 5,013·9ft. per minute. Indications of full load with a boiler pressure of 90lb. works out to 992·96 I.H.P. Indications of friction with the whole of the gearing and engines at work equals 310·1 I.H.P., giving 31·2 per cent. of friction. Description of gearing : New, not supplied by engine maker.

7th Examp'e —Horizontal compound tandem engine, high-pressure cylinder 19in. diameter, low-pressure cylinder 38in. diameter, 5ft. stroke, making 62 revolutions per minute, or a piston speed of 620ft. per minute, works out to 393·5 I.H.P. Indications of friction with the whole of gearing and engine at work equal 126·8 I.H.P., being 32·3 per cent. of the total load, leaving an actual load of 67·7 per cent. on the engine.

8th Example.—Pair of horizontal compound tandem engines, high-pressure cylinders 27in. diameter, low-pressure cylinders 46in. diameter, all 5ft. 6in. stroke, making 75 revolutions per minute, or a piston speed of 825ft. per minute. Rope pulley 22ft. diameter grooved for 40 ropes 1⅝in. diameter. Speed of ropes 5,183·6ft. per minute. Indications of full load with a boiler pressure of 100lb. works out to 1,579·52 I.H.P. Indications of friction with the whole of gearing and engines at work equal 389·4 I.H.P., being 24·6 per cent. of the total load, leaving 75·4 per cent. of an actual load on the engines.

N.B.—This engine is not fully loaded ; the shafting and engines were fixed to turn 2,000 I.H.P. The friction at this power equals 19·47 per cent. New gearing supplied by the maker of engines.

Belt Driving Engines.

1st Example.—Pair of horizontal compound tandem engines, with high pressure cylinders 18in. diameter, low-pressure cylinders 36in. diameter, all 5ft. stroke, making 53 revolutions per minute, or a piston speed of 530ft. per minute. Fly-belt pulley 26ft. diameter, 8ft. wide, for three belts 2ft. 6in. wide, giving a belt speed of 4,320ft. per minute. Indications of full load 855·95 I.H.P. Indication of friction with the whole of the gearing and engines at work equals 241·85 I.H.P., being 28·2 per cent. of the total load, leaving an actual load of 71·8 per cent. on the engines.

P.S.—There is some rope driving, gearing supplied by maker of engines.

2nd Example.—Pair of horizontal compound tandem engines, with high-pressure cylinders 26in. diameter, low-pressure cylinders 40in. diameter, all 5ft. stroke, making 47¼ revolutions per minute, or a piston speed of 472½ft. per minute. Fly-belt pulley 28ft. diameter, 7ft. wide, prepared for three belts each 26in. in width, and giving a belt speed of 4,158ft. per minute. Indication of full load with a boiler pressure of 85lb. works out to 969 I.H.P. Indication of friction with the whole of the gearing and engine at work equals 262·3 I.H.P., being 27 per cent. of the total load, leaving an actual load of 73 per cent. on the engines.

Direct-Acting Engines.

1st Example.—Horizontal single cylinder condensing engine, with cylinder 32in. diameter, stroke 3ft., making 91 revolutions per minute, or a piston speed of 546ft. per minute. Crank shaft coupled direct to second motion shaft. Indication of full load with boiler pressure of 80lb. works out to 503·85 I.H.P. Indication of friction with the whole of the gearing and engine at work equals 99·1 I.H.P., being 19·67 per cent. of total load, leaving an actual load of 80·33 per cent. on the engine.

P.S.—The gearing in this case is old.

2nd Example.—Inverted vertical three throw crank triple expansion engine, with high-pressure cylinder 14in. diameter intermediate 22½in., low-pressure 36in. diameter, all 3ft. 6in. stroke, making 65½ revolutions per minute, or a piston speed of 458½ft. per minute. Crank shaft coupled direct to second motion shaft.

Hosted by Google

stroke 5ft., making 58½ revolutions per minute, or a piston speed of 585ft. per minute. Rope pulley 28ft. diameter, grooved for 16 ropes, 1¾in. diameter, 10 ropes only being used. Speed of ropes, 5,146·9ft. per minute. Indications of full load with boiler pressure of 100lb. works out to 724·9 I.H.P. Indications of friction with the whole of gearing and engines at work equal 232·1 I.H.P., giving 32 per cent. of friction. Description of gearing: New, but badly arranged to assist in driving part of another mill; 24 ropes 1¾in. diameter used in driving in addition to main shafts.

3rd Example.—Pair of horizontal compound side-by-side engines, high-pressure cylinders 24in. diameter, low-pressure cylinders 48in. diameter, both 5ft. 6in. stroke, making 62 revolutions per minute or a piston speed of 682ft. per minute. Rope pulley 24ft. diameter, grooved for 24 ropes 1½in. diameter, speed of ropes 4,674·7ft. per minute. Indications of full load with boiler pressure of 110lb. work out to 859 I.H.P. Indications of friction with the whole of gearing and engines at work equals 274·2 I.H.P., giving 32·8 per cent. of friction. Description of gearing: Old, altered to suit rope driving was previously arranged for belt driving.

4th Example.—Pair of horizontal compound tandem engines, with high-pressure cylinders 22in. diameter, low-pressure cylinders 44in. diameter, all 5ft. stroke, making 55 revolutions per minute or a piston speed of 550ft. per minute. Rope pulley 28ft. diameter Indications of full load work out to 388·8 I.H.P. Indications of friction with the whole of the gearing and engine at work equal 94·5 I.H.P. at 68 revolutions per minute, being 28 per cent. of total load.

P.S.—The gearing in this mill is old and badly arranged from engine.

The conclusions to be drawn from the examples furnished, although not numerous and varied enough to pronounce a definite and accurate opinion upon, point to the fact that the engines would be found to be fairly efficient in themselves, but that the arrangement, construction, and the lubrication of the gearing is the principal defect. Two examples, No. 4 and No. 6, will prove this point. Example No. 6, engines were indicated without the gearing, the percentage of friction to the total load being 6 per cent., giving an efficiency for the engines of 94 per cent. of power to be transmitted through the crank shaft. Example No. 4, engines were indicated without the gearing, the percentage of friction to the total load being 10 3 per cent., giving an efficiency for the engines of 89·7 per cent.

The power in both cases is transmitted first by spur fly driving-wheel and pinion, afterwards rope driving is introduced; the friction of the gearing only in Example No. 6 being 18 per cent., the friction of the engines and gearing together being 24 per cent. of the total load. In Example No. 4 the friction of the gearing only was 25·3 per cent., the friction of the engines and gearing together being 35·6 per cent. of the total load.

By a reference to the summary it will be seen that the best results will be found in the gearing engine No. 8, but that No. 5 Example in the same class, and No. 1 in the direct-acting engines run it very closely.

The average percentages of the examples given show less actual work than I had expected to find, and I shall be pleased if any of the members will supply me accurate data or permission to indicate other examples for the purpose of revising this Paper and making it more complete. In conclusion I would say that the lessons to be learnt from carefully studying the examples are briefly as follows:—

That spur-gearing engines give the best result when not complicated with rope driving.

That rope-driving engines show the best results at high rope speeds, and that direct driving from the main drum is very desirable.

That belt-driving engines for developing large powers are only equal to the average rope-driving engine, with fewer advantages in other respects.

That the direct-acting type of engine is likely to be very efficient.

LEGAL INTELLIGENCE.

King, Brown, and Co. v. J. C. Gray.

The record has been closed in the Scotch Courts by Lord Kincairney in an action by Messrs. King, Brown, and Co. against James Cooke Gray, head master, Blairlodge School, Polmont Station, Stirlingshire, to recover £100 damages for alleged breach of contract.

The pursuers aver that in August last they entered into a contract with the defender for additions to the electric light installation at Blairlodge, but that on September 7th the defender refused to allow them to proceed with the contract, although a large amount of the work necessary for the carrying out of the contract had been put in hand.

The defender contends that no concluded agreement was ever come to, and that the letters founded on by the pursuers were merely instruments of negotiation.

The case was sent to the Procedure Roll.

National Electric Supply Company (Limited) v. Coward.

The National Electric Supply Company (Limited) have brought an action against a Mr. John Coward, innkeeper, of Friargate, Preston, to recover £14. 6s. 3d. for current for lighting purposes, and for rent of meter. The plaintiff's counsel said that the defendant had paid £4. 13s. 5d. into court as sufficient to satisfy the claim. Some time ago the defendant determined to have the electric light, and it was installed in June of last year. His first bill was sent in and he paid it, and subsequently he had two other bills. He then began to complain about the charges. He did not know what the defence was, but perhaps the defendant was going to try to impugn the meter. One had heard of the remark, "Lying like a gas meter," and it might be they would say, "Lying like an electric light meter." He should be able to satisfy the jury that the defendant's bill only came to the average according to the kind of light he used. A 16-c.p. light would cost ½d. per hour and a 32-c.p. would cost a third of 1d. It was absurd to pay £4 into court to satisfy the claim; people could not expect to have twice the light for the same money.

John Carr Rose, meter inspector for the Company, said the defendant's was an Aron meter. It was an approved instrument, which had obtained some prizes in national contests. It was an accurate meter. It was correct when it was put in, and he examined it from time to time to take the record. The bill was made out on his record. Ultimately, at the beginning of this year, it was taken out. It was working accurately on January 7th, and he took the record then. There had been no debit of the supply of light since January 7th. The bill of £14. 6s. 3d. included £12. 12s. 3d. for current, £1. 3s. 7d. additional up to January 7th, and the rest was for use of meter.

The meter was produced in court, the witness explaining the mechanism of it.

The defence was that there was a mistake between the parties as to the contract under which the light was put in. He had an understanding with the Company's representative that he was to have his light as cheap as the gas. The bills were satisfactory until the putting in of the meter.

Hosted by Google

after which the bill jumped up to over £14. Then he began to grumble, and found that his friends were being charged much less sums, and in consequence one other innkeeper had his supply cut off. They changed his meter, and it registered more than before. Afterwards defendant's meter was disconnected, and after that the meter went on registering just as before. That being so, it was fair to assume that it had given a false record all along.

Witnesses were called in support of the defendant's case; but, after a lengthy hearing, the jury found for the plaintiff for £13. 6s. 9d.

CORRESPONDENCE.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: If I take up my pen to comment upon the manifesto of Messrs. Erskine, Manville, Mavor, Raworth and Swinton, respecting the composition of the Council of the Institution of Electrical Engineers, it is not at all to formulate any reply to the indictment framed by these good men and true; I merely wish to complete their statement, which, it is well known, embodies partially sentiments that exist pretty widely in the Institution within the Council as well as without. In other words, there are members of the Council who, as individuals, recognise, perhaps even more clearly than do Messrs. Erskine, Manville, Mavor, Raworth and Swinton, the shortcomings which they have in part pointed out. As it is, in the natural course of things, my turn to retire from the Council in six weeks' time, I can speak the more impersonally. The object dear at heart to the memorialists can, therefore, in one instance, be readily attained without friction.

Let me first begin by classifying a little more definitely the membership of the Council. I take the official list, as the memorialists did; but, alas, we have just lost Mr. Graves! As the term electrical engineer has no legal or recognised definition, and as every gasfitter is nowadays an electrician, I avoid these indescriptive terms. In passing, I remark how strange it is that the memorialists are able to discover no fewer than ten professors who are neither "electricians" nor "electrical engineers." Perhaps Prof. Hughes never was an electrician, in spite of his well-known inventions. Perhaps Prof. Hopkinson never was an electrical engineer. But in that case—dreadful thought—who is? However, let that pass.

The Council, including past Presidents and Vice-Presidents, consists, indeed, of the following:—

Manufacturers and contractors	5
Telegraph, telephone, and cable men	13
Chemists	2
Engineers in consulting practice, not included in above	6
Baronets	1
Engineers to manufacturing firms	1
Government officials, not included in above	2
Teachers of electricity, not included in above	2
	32

or, omitting past Presidents and Vice-Presidents,

Manufacturers and contractors	2
Telegraph, telephone, and cable men	5
Chemists	0
Engineers in consulting practice, not included in above	5
Baronets	0
Engineers to manufacturing firms	1
Government officials, not included in above	2
Teachers of electricity, not included in the above	0
	15

Inspection of these figures at once shows on what head the Council is overweighted. But, then, the Institution must be forgiven for the circumstance that it originated as a body of telegraph engineers, and not as a body of manufacturers or contractors.

But really there is a grain of reason in the contention that there are in the Institution and on its Council gentlemen "only indirectly connected with practical engineering." Too often the phrase "practical engineer" is held to denote one who has served seven years of drudgery at the bench. Well, but that is precisely (my friends will pardon me for so personally using them as examples) what my friend John Perry, engineer and Professor, did; it is precisely what my friend William M. Mordey, engineer and inventor, did not do. It is within the bounds of possibility that there may be contractors and manufacturers who are even less directly connected with practical engineering.

It is a pity for the memorialists' case that they have so sadly understated the "professorial element" on the Council. Their delicately-concealed suggestion that if a man has at some time or other held a responsible post as a teacher that circumstance in some way disqualified him to take part in managing a "professional" body such as the Institution, reaches more widely than to the 10 "professors" (including Lord Kelvin) so denominated in the official list of the Council. To these ten should be added Prof. Sir Frederick Abel, Prof. John Hopkinson, Prof. (now General) Webber, and Prof. Crookes, not to add Mr. Mordey and Mr. Swinburne, both of whom have qualified themselves for the same courtesy title by systematic teaching. So the 10 should be written 16. It is evidently high time that the number of "professors" on the Council should be reduced. There is also an undue proportion of members of Council whose names begin with the letter C. Moreover, compared with the civil engineers there is a smaller proportion of "Sirs" on the Council. This is a sad oversight which might be commended to the notice of the P. M. G. (I do not mean the *Pall Mall Gazette*).

What seems to be the saddest fault of all is the complete absence from the Council of any person who, being neither an engineer in consulting practice, a teacher, a soldier, a sailor, an officer in the volunteers, a government official, a company director, a company promoter, a cable man, a telegraph operator, a chemist, an author, a peer, or a baronet, and never having been any one of these things, shall be therefore competent to represent "those actively engaged in constructive work." The omission is not, however, irremediable. Doubtless the Council, awakened at last to a sense of its shortcomings, will fill one of the shortly vacant places by the member entitled to such unique distinction—if he can be found.—Yours, &c.,

SILVANUS P. THOMPSON.

LECLANCHÉ BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your article in last week's issue upon "Improvements in the Leclanché Battery," and in which you specially refer to the new Leclanché-Barbier Patent Cylindrical Cells, which I am now introducing into this country, will you allow me to state in correction of the concluding paragraph of the article that Messrs. Leclanché and Co. have granted me the sole concession to sell in Great Britain and the Colonies their Patent Cylindrical Agglomerate Batteries of both the wet and dry patterns, any such rights previously held by others in this country having been lately terminated in my favour.—Yours, &c.,

R. AYLMER.

47, Victoria-street, London, S.W.

SUNSPOTS, MAGNETIC STORMS AND AURORA BOREALIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It occurred to me while reading Prof. Fitzgerald's letter, and your Editorial Note thereon, that the phenomenon aurora borealis, which, if I mistake not, is usually, if not invariably accompanied by a magnetic storm, may in reality be the attenuated tip or tips of the flame-like protuberances called the corona, or the projected electrified matter streaming past our planet, the actual "licking" probably taking place on a portion of the earth's surface on which the sun's light would prevent observation. If this were so, aurora borealis would be more generally observed near the northern or southern poles, as it is not because of the magnetic polarity of the earth, but simply because of the sun's position below the horizon.—Yours, &c.,

W. B. SAYERS.

Glenwood, Bearsden, N.B., Nov. 14, 1892.

Submarine Telegraphy in Japan.—It is reported that the Japanese Communications Department has decided upon the construction of a steamer for cable-laying purposes.

THE CABLE SERVICE TO AUSTRALIA.

(From *The Times.*)

A difficulty has arisen between the Australasian Governments and the Government of India in regard to the transit rate to be levied by the latter upon Australasian cable messages passing over the Indian land line from Bombay to Madras. At first the rate charged was £9 9s. 6d. for 20 words, but it has been gradually reduced until it is now 4s. a word. In consideration of the great risk involved in the last reduction it was agreed that the Eastern Extension Telegraph Company should be guaranteed by the Australian colonies a revenue equal to that received in 1889, half the deficiency, if any, to be borne by the cable company. It was further agreed that South Australia should be guaranteed a revenue equal to 1889 on the transcontinental line. The result of the experimental trial for the first twelve months was a decrease in the receipts of the cable company of £55,040, and to South Australia on the transcontinental line of £10,415. The proportion of loss borne by the cable company was £27,520, and by the guaranteeing Colonies (who were also responsible to South Australia), as follows:—Victoria, £15,508; New South Wales, £15,397; South Australia, £4,357; Tasmania. £1,994; and Western Australia, £676. Since then New Zealand has accepted a share of the financial responsibility, but Queensland still holds aloof. Chiefly at the instance of New South Wales, the Australasian colonies have quite recently decided to raise the tariff by 9d. a word, making the through rate 4s. 9d. a word. The European nations who were concerned in the change raised no objection, but India has created an awkward difficulty, the removal of which was the object of a deputation which waited upon the Colonial Office on Tuesday. Until recently the transit rate of 75 centimes a word was charged for the transmission of messages between Bombay and Madras. The Indian Government last year reduced the transit rate to 35 centimes a word. The negotiations with the Australian colonies were at that time being conducted on the basis of a tariff of 5s. a word, but afterwards the cable company consented to try the experiment of a 4s. tariff. It was therefore submitted to the Earl of Kimberley and the Marquis of Ripon on Tuesday by the Agents-General for New South Wales, Victoria, Tasmania, South Australia, New Zealand, and by Sir John Pender, the Chairman of the Eastern Extension Company, who accompanied the deputation, that the imposition by the Colonies of an additional 9d. a word, in which the Indian Government had acquiesced, would not justify the latter in increasing the transit rate as against Australasian messages from 35 to 50 centimes a word. It was argued that the effect would be to place the Colonies at a decided disadvantage as compared with countries further east. The deputation contended that the additional 9d. would scarcely exercise any appreciable influence on the tariff, and would only temporarily retard its development. India had benefited by the reduced tariff of 4s. a word, which had increased the Australasian traffic by over 60 per cent., without involving India in any of the sacrifices borne by the Colonies and the Company. Lord Kimberley was urged to use his influence with the Government of India to secure the withdrawal of their proposal and avert the possible retirement of the Colonies from an arrangement which had proved so beneficial to commerce.

The SECRETARY of STATE for INDIA promised to bring the arguments of the deputation to the notice of the Government of India. He hoped he might be in a position to indicate their reply in time to enable the amended tariff to come into operation at the beginning of the new year.

The deputation thanked Lord Ripon, in whose office the interview was held, and Lord Kimberley, and withdrew.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The Local Authorities of Paisley invite tenders for the transfer of the powers conferred by the Paisley Electric Lighting Order, 1891. All particulars may be obtained of Mr. Bryson, 11, Bothwell-street, Glasgow; and tenders must be delivered to Messrs. Young and Martin, town clerks, Municipal-buildings, Paisley, by the 28th inst.

——— CLOSING OF CONTRACTS.—Readers are reminded that tenders for the supply of electric lighting plant for the City of York have to be in by the 21st inst.; for wiring the Town Hall, Hove, Sussex, this day (Friday), 18th inst.; and for the installation of wires, switches, &c., for the new Police Station at Blackpool, by the 28th inst.

TENDERS ACCEPTED.—The Burnley Corporation have accepted the following tenders for the supply and erection of electric lighting plant :—

Electric Construction Corporation (Limited)—dynamos, accumulators, and switchboards	£2,056
Callender's Bitumen, Telegraph, and Waterproof Company (Limited)—electric cables	4,537
Burnley Ironworks Company (Limited)—engines	1,600
Oldham Boiler Works Company—boilers	700
Messrs. E. Green and Son—economisers	228
Job Isles, Stanningley—cranes	195

BUSINESS FOR DISPOSAL.—Messrs. Wheatley Kirk, Price and Goulty have an old-established engineering business for sale at an exceptionally low price to an immediate purchaser.

APPOINTMENT.—Mr. W. A. Valentine has been appointed district manager of the New Telephone Company at Manchester, *vice* Mr. G. J. Someville, who comes to London to take charge of the metropolitan district.

BELL'S ASBESTOS COMPANY (LIMITED).—This firm have removed to their new premises and offices at Southwark Bridge House, Southwark-street.

IN RE VICTOR SILBERBERG.—Mr. T. W. Gilbert, the trustee under the bankruptcy of this debtor, announces the payment of a first and final dividend of 2s. 6½d. in the pound, payable on Thursday, the 17th inst., or on any subsequent Thursday, between 11 and 3. The estate realised £236. 10s. 2d., out of whic creditors will receive £114. 5s. 5d., the cost of realisation being £112. 4s. 10d.

PATENT EXPERTS.—A "patent expert to the British and Foreign Governments" writes to us from Chancery-lane and informs us that as many of the Council of the Institution of Electrical Engineers "testify to the value of patents" in so unsatisfactory a manner he has decided to raise his fees very considerably, and trusts that we will permit him to offer us a commission of 5 per cent. on any business resulting from our introductions, but he wishes it to be distinctly understood that he will never testify to any unsound affair, or in any way use such influence as he may have to get any patents, &c., taken up by any Government. In the course of his letter, which being marked "not for publication," we cannot give in full, he incidentally remarks that he can assure us that there are more quacks than Harness! He seems to be an authority on this subject. We do not know how to refuse the permission which he petitions.

THE E. P. S. STORAGE BATTERIES.—We have received a notification from the Electrical Power Storage Company (Limited) that a further order for their E. P. S. accumulators has been received from the London, Brighton, and South Coast Railway Company, who have decided upon lighting another seven trains on their system, making 30 trains in all. In addition the E. P. S. Company have received an intimation that a considerable extension of train lighting is likely to be adopted by the Brighton Company in the near future.

THE GUILDHALL LIGHTING.—This installation is now complete, and comprises the Guildhall Council Chamber, the Lobby, and the Corporation Library and Reading Room. In the main building 540 glow lamps are installed, nearly 400 of which are 16 c.p. The beautiful gas pendants, designed by Horace Jones, have been cleverly and tastefully adapted for the electric light, and when on a recent occasion the current was switched on, the effect was very pleasing to those present. The result of the installation is that the Hall is now brilliantly illuminated. At the Lord Mayor's banquet, last week, the Guildhall presented an appearance such as has never before been witnessed. On the occasion of the children's *fête*, which was of considerable magnitude, on the 11th, the electric light added considerably to the beauty of the scene. In the Council Chamber a large centre fitting is provided with 78 bulbs, 60 of 25 c.p., and 18 of 16 c.p., tastefully and systematically arranged. The two large standards, one on each side, are fitted with 13 16 c.p. lamps each, a nine-light fitting being provided for the reporters' gallery. The architectural beauties of the Chamber are well brought out, and an efficient light is provided for every corner of the large space. For the lobby four pendants are used, each with four 25 c.p. lamps. The whole of the pendants have been adapted from the previous gas fittings, and such other fittings as have been required have been supplied by the Electrical Accessories Company (Limited.) The whole of the work has been carried out to the entire satisfaction of Mr. W. H. Preece, and reflects credit upon the contractors, Messrs. Lund Brothers, of Oxford-street, W.

MESSRS. J. AND W. WEEMS.—This firm have just had delivered a casting of a cylinder, weighing 21 tons, which forms a section of a lead press weighing more than 60 tons when completed. This is the largest lead pipe press ever made by this firm, and is used for the enclosing of cable and all classes of electric wires into lead pipes.

RYLANDER AND RUDOLPHS FABRIKS-AKTIEBOLAGS.—We have received from this Swedish firm an illustrated price list of their battery elements, &c. Their speciality is carbon for all kinds of electrical work.

THE STANHOPE COMPANY.—This Company are issuing a pamphlet dealing with their water purifiers and softeners, containing details of the advantages claimed by the Company for their manufactures. At the end, a list is given of the principal users, which includes a number of electric light companies.

Hosted by Google

MESSRS. CHRISTY BROS.—This firm have recently completed contracts for several mill-lighting installations, amongst which is a complete plant for 200 lights for Messrs. J. and H. Robinson, of Greenwich (with a number of hand lamps of a new and improved type), and extensions to the mills of Messrs. E. Marriage and Sons, Colchester, and Messrs. Lofthouse and Hammond, of Boroughbridge. Also a 400-light plant for Stockport, a 300-light plant at Maybole in Scotland, and a large combined arc and incandescent plant in a mill at Purfleet. They are busy with a "new application of electricity" in a large clothing factory near Bath in the shape of a large number of electric "geese and irons" for ironing garments.

BRADFORD GAS ENGINES.—Messrs. S. Clayton and Co. send us their illustrated price list of Bradford gas-engines, with a long list of users and testimonials therefrom.

COMPANY'S STATISTICS.—Messrs. Faithful Begg and Co., of Bartholomew House, E.C., have recently issued an interesting sheet giving some financial particulars relating to electric supply and manufacturing companies. The information given is limited to a few leading companies, and is similar to that to be found in "The Electrician" Blue Book.

ELECTRO-HARMONIC SOCIETY.—On Friday, the 25th inst., a "Ladies' Night" Concert will be given in the Banquet Room of the St. James's Hall Restaurant, Regent-street, W., at eight o'clock.

ARUNDEL CASTLE.—The contract for the electric lighting of Arundel Castle, the seat of the Duke of Norfolk, has been secured by the Brush Electrical Engineering Company. It comprises some 1,200 lamps of 16 c.p. for the Castle, together with lamps for the drive and the courtyard. The generating station will be about 500 yards from the Castle. The dynamos are specially wound for this purpose, and are over-compounded for a maximum loss of 13½ volts in the mains.

AYR.—The Town Council, notwithstanding that some time ago they obtained powers to introduce electric lighting into the town, have made little or no progress, to the disappointment of many intending consumers, and private firms are making a number of installations in the district.

BARNARD CASTLE.—On Thursday last the members of the Local Board had under consideration with a representative of the Brush Company the subject of the preparation of an estimate for lighting the town with electricity and the extension of the lighting to the North Eastern County School.

BELFAST.—The Gas Committee have postponed for a further week the appointment of a consulting electrical engineer.

BURNLEY.—At the last meeting of the Town Council it was argeed to adopt the recommendations of the Gas Committee for the placing of the tenders for electric lighting plant, &c., required for the Burnley lighting. These tenders are given in another column. Alderman Collinge said the Gas Committee were anxious that the tenders should be placed over. To save time they had already commenced the building of the electric lighting station and expected to have it finished next spring, and they hoped to supply the light by midsummer. About 200 tenders have been received and, notwithstanding their desire to place the order with one firm, they found that so much would be saved by breaking it up and accepting various tenders for the work, that they had decided upon that course. They had anticipated the cost would have been about £19,000 where the tenders came to £14,500. They had power to borrow £23,000 for the purpose. They gave the tender for the boilers to a Burnley Company as, although they were not the lowest, they were within a little of some of the best engineers in the country, and the Committee were desirous of keeping the work in the town. The area of supply would be about 2,000 yards. Everything was in duplicate, even the engines, so that any possible breakdown was provided against.

BURTON-ON-TRENT.—The Town Council have decided to apply for permission to borrow £80,000 for the purpose of electric lighting and sewerage.

COATBRIDGE.—In reference to a statement that no progress is being made with the Electric Lighting Company's works at Coatbridge, it is explained that certain statutory notices expire on the 28th inst., and that until their expiry nothing can be done. The plant manufacturing work is being actively proceeded with.

DUNDALK.—A special meeting of the Town Commissioners was held last week to consider the reply by the Board of Trade for their application of the renewal of the Electric Lighting License of 1885, which expires on July 1st next. The Board of Trade recommended an application for a Provisional Order, and this is supported by the solicitor of the Commissioners. It was decided to adjourn the consideration of the matter till April next.

HOWTH.—A meeting has been held of those interested to consider as to what steps should be taken to light some of the principal streets by public voluntary subscriptions. A scheme is to be drawn and submitted to a public meeting at a future date.

KINGSTON—The Electric Lighting Committee of the Town Council has been re-appointed, and Mr. Shoolbred's report has been received. At the last meeting a copy of this report was ordered to be furnished to each member of the Committee. The new county buildings are being lighted electrically, but complaint is made of the slow progress of the Corporation in dealing with the matter.

MORPETH.—The East Mills have been lighted electrically by Messrs. Wynne and Barnard, a D type dynamo being driven by the large water-wheel of the old mill.

NEWCASTLE.—At the re-opening of the Art Gallery at Newcastle on Friday last, the National Telephone Company supplied 40 telephones, by means of which music was supplied from Sheffield, Bradford, Liverpool, and Sunderland, to the enjoyment of the numerous visitors.

NEWPORT.—The Sub-Committee of the County Council reported the result of their visit to St. Pancras, and stated that Prof. Robinson had offered to furnish them with a report as to the best mode of setting about their local installation for the sum of £50. Ultimately the subject was adjourned till the next meeting.

PENARTH.—A meeting of the Local Board was held on Monday last to discuss the desirability of lighting the town with electricity. A plan was submitted showing the principal streets proposed to be lighted. The Company, which is being formed to undertake the supply, offer the Board to light the Municipal offices at the same price as gas. The Company also offers to light the principal thoroughfares at a price under £3 per lamp per annum. The proposal was favourably received, but it was decided to obtain information from other Local Authorities before proceeding in the matter.

REDRUTH.—Considerable activity is shown in this district with the electric light, several large blocks of business premises being lighted. Messrs. Tangye have recently placed a memorial stone on the house which was once occupied by W. Murdock, who first invented gas, and was a resident in the neighbourhood a hundred years ago.

SHOREDITCH.—Mr. E. Manville, of Messrs. Waller and Manville, has been appointed consulting engineer of St. Leonard's, Shoreditch, to advise a Parliamentary Committee on their proposed lighting undertaking. At the meeting of the Vestry last week it was decided to seek the advice of an expert as to whether the supply of electricity can be advantageously undertaken by the Vestry, at what cost, the best system to adopt, the best site to select, and the capital required. It was also decided that a committee visit some of the leading stations to compare results.

SIAM.—The affairs of the Siam Electric Light Company are to be satisfactorily settled, £20,000 having been advanced by the Siam Treasury, out of which the creditors are to be paid. The Brush Company, on receipt of the first instalment awarded by the recent court of arbitration, will send out a staff of men to put the machinery in order, after which the balance due to them will be paid. The concern will then either be put up to auction or taken over by the Government by private arrangement with the Company.

WESTON-SUPER-MARE.—The subject of electric lighting came on for discussion at the meeting of the Town Commissioners last week. The Inspection Committee recommended that the Board should be prepared to consider any proposition which may be made for the lighting of the town by electricity.

WINDERMERE.—The Local Board have appointed Messrs. Irving, Harrison, and Garnett, members, to report on the subject of the electric lighting of Windermere, and upon the opening of the streets for the laying of electric light mains.

WITHINGTON.—It has been decided by the Local Board to appoint a special committee to inquire into the subject of lighting the district by electricity, and to report thereon.

COMPANIES' MEETINGS & REPORTS.

West India and Panama Telegraph Company (Limited).

The 31st ordinary general meeting of the members of this Company, was held at Winchester House, Old Broad-street, E.C., on Tuesday last, Mr. C. W. Earle presiding.

The SECRETARY (Mr. R. T. Brown) read the notice convening the meeting, and the minutes of the previous meeting, the latter being approved and signed as correct.

The Directors' report and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, although the report is one announcing a decrease of £3,493 in revenue, and an increase of £3,721 in expenditure, it is a somewhat better account on the whole than I anticipated. When we were discussing the effect of the reduction of the tariff, which we were impelled to make this time twelve months, if you had asked me whether we were going to pay even the insignificant dividend of 6d. a share on the present occasion, I should certainly have said that I thought not. When we came to our meeting in May last, and had to announce a decrease of £7,350 in our traffic receipts, I was still more confirmed in this unfavourable view of our position. However, from this report it will appear that this six months we have only had a decrease in our traffics of £3,762, which is much less than we expected to have. Now, in comparing the different periods with the view of ascertaining to what extent the diminished tariff that we made in June, 1891, has had on our receipts, there is always the uncertain factor of the ebb and flow of West Indian trade, and I think that the period which we are reporting on now was better in the matter of West Indian trade than the corresponding one of the previous year. I feel pretty confident myself that the reduction we made in the tariffs, amounting to 20 per cent. at most of the stations, has not produced a single extra message over our lines. That, I think, we were all prepared for, because we know very well that people are not in the habit of telegraphing for the fun of the thing. They only send messages which cost them several pounds when they have matters of importance to deal with. Whether a message costs £5 or £3 it has to be sent, and it is just as likely that we should have as many messages at the one tariff as at the other. Therefore, I do not think that the reduction we made in consequence of the competition brought against us would have any effect in the way of an increased volume of traffic. I think our competitors, who invaded our field in so unnecessary a way, must be rather sorry that they have spent their money in laying cables to the West Indies. Their report to last December—they issue a report only once a year—was a very unsatisfactory affair, and I suppose that next year it will be worse. Their line to the Brazils is broken down. It brought them very little traffic, and if they attempt to repair it there will be a great expense involved. At the present moment they have no ships in the West Indian station for repairing purposes, and I have not heard of their sending one out to mend that cable.

Looking to the expenditure side of the account, and to the details of the repairs to cables, which are summarised in abstract "C," I find that we have had 15 interruptions during the half-year that we now report upon, as against seven in the same period of the previous year; and that we used 190 knots of cable in effecting those repairs as against 44 in the corresponding period of 1891. Now that, of course, will explain to you the very large increase in the expenditure on cable repairs. Of these cables, the principal offender was the old one between Jamaica and Porto Rico, which failed in a very great depth of water, namely, 2,234 fathoms or 2½ miles. As it is an old cable, having been down 22 years, it was found not to have sufficient mechanical strength to enable the ship to lift it to the surface. It kept constantly breaking, and the consequence was that our ship had to travel along the cable until it came to ground where the soundings were more favourable for picking up, and the points at which they did get the cable necessitated the laying on of a piece measuring 85 knots in order to effect the repair. A similar case, only to a much less extent, occurred in the Grenada-Trinidad cable, but only 19 knots were expended in that instance. These repairs amount to renewals, and we have followed the practice that we have always followed on previous occasions with repairs of such magnitude, and have charged the cost of the cable to the reserve fund which was established for that very purpose.

The report announces that our steamship "Grappler" has been ordered home to London to be surveyed and fitted with a new boiler. This vessel has been actively in our service for 12 years, and after that time it is considered by prudent people, and it is in accordance with Lloyd's requirements, that the boiler must be renewed, which we intend to have done. The only other point that I have to remark upon is the vacancy that has been caused on this Board by the death of Mr. Ford, whose loss I still continue to feel very much. I should have been very glad indeed to have had Mr. Ford's advice and wise counsel to assist us in our management of this half-year. Seeing the great difficulty which there would be in replacing him, we have thought it advisable not to fill up the vacancy. This will be a small economy to the Company, and, on the whole, we think that is the proper course to pursue in our present circumstances. I shall now be very glad to answer any questions you wish to put to me, and in the meantime I beg to move—

"That the Directors' report and accounts to June 30, 1892, submitted to this meeting, be and the same are hereby received and adopted, and that, as recommended by the Board, dividends of 6s. per share on the First Preference shares, 6s. per share on the Second Preference shares, and 6d. per share on the ordinary shares, the last being free of income-tax, be and the same are hereby declared."

Hosted by Google

Sir JAMES ANDERSON seconded the motion.

A SHAREHOLDER asked whether any comparative statement could be given as to the takings since the close of the accounts.

The CHAIRMAN : They show a slight improvement. I think, as nearly as possible, it would be £1,700 more than we had up to the present time last year. At the same time I may say, as a source of further comfort, that our repairs are very much less this half-year.

Mr. CHAMBERLAIN wished to point out that, whereas the repairs to cables amounted to something like £11,000 extra, three-fourths of the amount was charged to the reserve fund and only one-fourth, in round numbers, to current expenditure. With regard to the "Grappler," had the Board considered the advisability of fitting her with triple-expansion engines? Her coal bill must be a very serious item. In the revenue account one of the items was the cost of issuing debentures and obtaining a Stock Exchange quotation, £573. These, he presumed, were the £80,000 Debentures bearing 5 per cent. Would the Chairman kindly tell them whether these were redeemable after a term of years?

The CHAIRMAN : They are issued for 25 years. The cost of issue is an exceptional item. It might have been spread over the 25 years, but we thought it was hardly worth while to do so. We thought it better to get rid of it at once. The principal part of the expenditure was £400 in stamps, printing £50, and the Stock Exchange quotation. With regard to Mr. Chamberlain's other inquiries, as to charging the renewal of our cable to the reserve fund, the latter is based upon a calculation that we make of how long a cable has got to last, and at what rate we should renew it, and also what rate of interest we receive for our reserves ; and our reserve fund stands up to the level it ought to be at in the twenty-third year of our cable's existence, therefore it is a perfectly fair charge. Remember, we laid nearly £7,000 worth of new cable, and charged it to revenue, and the system is bettered to that amount. The question of triple-expansion engines was fully discussed, and the matter reported upon by our surveyor, who decided not to recommend these engines.

In further reply to a SHAREHOLDER,

The CHAIRMAN added that their cables were all duplicated except the Colon one.

The resolution was then agreed to *nem. con.* ; and a vote of thanks having been passed to the Chairman and Directors, the proceedings terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

BURGLAR AND FIRE ALARM COMPANY (LIMITED).—This Company has been registered with a capital of £20,000, in 18,000 ordinary and 2,000 Ten per Cent Preference Shares of £1 each, to acquire, develop, and turn to account patents and inventions, particulars of which are not given, and to construct, originate, create, participate in, contract for, develop, administer, control, and manage electric, telegraphic, telephonic, tramway, railway, &c., undertakings and works.

ELECTRICAL WONDER COMPANY (LIMITED).—This Company was registered on November 12th, with a capital of £10,000, in 9,900 ordinary and 100 founders' shares of £1. The founders' shares will receive one-half the net profits remaining after the payment of a dividend of 10 per cent. per annum on the ordinary. The objects are :—To adopt and carry into effect an agreement dated November 4th, 1892, between Edgar Cohen and Howard Felgate (as trustee for, and on behalf of, the Company), for the acquisition of all the rights of the said Edgar Cohen in respect of the Electric Schnelsehed Automatic Apparatus, and to carry on the business of proprietors of automatic and other machines and apparatus, licensees, and exhibitors, caterers for public amusement, by the exhibition of any scientific, photographic, or other apparatus. The signatories are :—

	Shares.
Edwin Howell, Swiss Villas, Hall-road, Peckham Rye, London, E.C.	1
Edgar J. Cohen, 37, Bedford-square, London, W.C.	500
Henry Haufmann, Dashwood House, 9, New Broad-street, London, E.C.	10
Oscar Schölzig, Dashwood House, 9, New Broad-street, London, E.C.	250
Otto Schölzig, 31, Binfield-road, Clapham-road, London, S.W.	250
Percy James, 35, Benyon-road, Southgate-road, London, N...	1
Thomas E. Polden, 2, Amen-corner, London, E.C.	500

The first Directors are Arthur Schwarz, of Dashwood House, New Broad-street, E.C. ; T. E. Polden ; Count Max Hollender, of 135, Sutherland-avenue, London ; and Edgar Cohen.

METAL REDUCTION COMPANY (LIMITED).—This Company has been registered with a capital of £100,000, in £1 shares, to enter into an agreement with the Metal Reduction Syndicate (Limited) for the acquisition of its business ; to carry on the business of manufacturing, smelting, refining, selling, dealing in, and making merchantable metals of every description, and to carry on the business of electrical and mechanical engineers, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of, and dealers in, all apparatus and things required for or capable of being used in connection with the generation, distribution, accumulation, supply, and employment of electricity.

BARRY AND CARDIFF ELECTRIC LIGHT AND POWER SUPPLY (LIMITED).—KIDDERMINSTER ELECTRIC LIGHT AND POWER SUPPLY (LIMITED).—With reference to these companies, in answer to inquiries from the Registrar of Joint Stock Companies, Robert McA. Inglis, the secretary, notifies that the companies are not carrying on any business, that it is not the intention of the promoters to proceed further with them, and that they can be dissolved.

ELECTRICAL COAL-CUTTING CONTRACT CORPORATION (LIMITED).—The statutory return of this Company made up to Sept. 28, 1892, has been filed. The Company was registered on June 18, 1892, with a capital of £402,000, divided into 60,000 ordinary shares of £5 each, 20,000 deferred shares of £5 each, and 2,000 founders' shares of £1 each. At the time of making up, 8,082 ordinary, 20,000 deferred, and 2,000 founders' shares were taken up, of which 4,000 ordinary and 20,000 deferred shares were issued as fully paid. Upon the remaining 4,082 ordinary shares £3. 10s. per share has been called, and upon the 2,000 founders' shares the full amount per share has been called, resulting in the payment of £15,237, leaving £1,050 as yet unpaid.

"ENERGY" GAS ELECTRIC LIGHTING AND POWER COMPANY (LTD.).—An agreement dated August 29, 1892, between the above-named Company and the Clamond Incandescent Gas Light Company (Limited) (in liquidation) and Ernest H. Hindley and Edward T. Read, the liquidators of the said Company, states that the Energy Company has recently agreed to purchase certain patents belonging to the Clamond Company from Charles Clamond and Louis Denayrouze in consideration of the allotment of 16,000 fully paid £1 shares, of which 5,734 were to be allotted to the Clamond Company, and it is agreed that the Energy Company shall allot the said 5,734 shares (numbered 8 to 5,741 inclusive) to the Clamond Company in full satisfaction of all their claims on the said patents. The Energy Company was registered on August 1, 1891, with a capital of £20,000, in £1 shares, to make gas light cheaper, give it the appearance of electric light, and generally to create by all practical means a lighting industry having the qualities of electricity and of gas without the disadvantages of either.

HOME TELEPHONE COMPANY (LIMITED).—The first annual return of this Company, made up to March 28, 1892, has been filed. The statutory return, made up to December 31, 1891, was filed on July 20th following. The Company was registered in July, 1891, with a capital of £500, in £5 shares. At the time of making up all the shares had been taken up, £1 per share called, and all calls (£100) paid.

ROPER'S ELECTRICAL ENGINEERING COMPANY (LIMITED).—At extraordinary general meetings of this Company, held at Bradford on Oct. 19th and Nov. 4th, the following resolution was passed and confirmed :—"That the Company be wound up voluntarily under the provisions of the Company's Acts, 1862, and subsequent Acts, and that William Martello Gray, of Bradford, in the county of York, chartered accountant, be and he is hereby appointed liquidator for the purposes of such winding up."

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended November 13 were £945, as against £819 for the corresponding period of last year, being an increase of £126. The total receipts for half-year amount to £16,108, against £14,575 in the corresponding period of 1891, being an increase of £1,533.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—Our advertisement columns contain a list of the numbers of 328 Five per Cent. Mortgage Debentures which were drawn on the 14th inst. for payment at par on January 2nd next.

THE ELMORE COMPANIES.—A Mr. T. Satchwell, writing to the financial journals, declares his intention (after the decision in the case of "Russell *v.* Mockford") to take action against the Directors of two of the Elmore Companies,. In reference to this matter, Mr. J. Shurmer, the Secretary of the Companies, writes that Mr. Satchwell has no interest in the companies, and that shareholders can obtain all particulars of the improved prospects of the Company at the Companies' offices in Cannon-street.

HOVE ELECTRIC LIGHTING COMPANY (LIMITED).—Notice is given that the statutory meeting of the shareholders of this Company will be held at the registered offices, Mansion House Buildings, E.C., on the 21st inst , at three o'clock. Messrs. Crompton and Co. have carried out the first portion of their contract with this Company, and the temporary station is practically complete. Two miles of mains have been laid, and everything done to the satisfaction of the Hove Commissioners. The actual supply of current will commence during the present week. Meanwhile, from the applications received for the light the Directors feel that the future success of the Company is assured.

MESSRS. DORMAN, LONG, AND CO.—The gross profit for the year ending September 30th was £53,853, making, with balance from last year, an available sum of £55,688. A dividend of 4s. per share is proposed, after paying off debenture interest and writing off for depreciation £15,658, carrying forward £3,439.

SOCIETE ANONYME D'ECLAIRAGE ELECTRIQUE DU SECTEUR DE LA PLACE CLICHY.—At the general meeting held recently in Paris it was stated that the demand for the electric light was increasing very satisfactorily. The working for the nine months ended June 30, 1891, had shown 9,517 lamps in operation, there being a loss for that period of 20,647fr. ; but at June 30th this year 29,522 lamps had been installed, and the balance of receipts over expenditure for the year 1891-92 had not only wiped out this adverse item, but had left 178,636fr. to the good. Out of this sum a dividend of 4 per cent. was declared. At a subsequent

Hosted by Google

extraordinary general meeting it was decided to increase the capital of the Société by 1,000,000fr.

SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—Subject to audit, the Directors have resolved to recommened the shareholders to declare a dividend as follows for the year ended September 30, 1892:—4s. 2⅔d. per share on the ordinary shares of the Company (£3. 10s. paid) and 4s. 11⅔d. per share on the £5 fully-paid shares, free of income-tax. This, together with the interim dividend paid on May 31st last, will make a total distribution of 10 per cent. for the year on the ordinary (£3. 10s. paid) shares of the Company. The dividend will be paid upon the register as it stood on Wednesday, and the warrants will be issued on December 13th.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Nov. 11, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,816.

WESTERN UNION TELEGRAPH COMPANY.—This Company has now declared an extra dividend of 10 per cent. in stock, payable on December 3rd. The Company's books close to-morrow (the 19th inst.).

TELEGRAMS: "INDICES," LONDON.

WHEATLEY KIRK, PRICE and GOULTY

(ESTABLISHED 1850).

ELECTRICAL AUCTIONEERS, VALUERS,

AND ARBITRATORS.

49, QUEEN VICTORIA STREET, LONDON, E.C.

And Albert Square, MANCHESTER.

SALES BY AUCTION, &c.

Re A. B. Gill and Co.

SALE of ENGINEERING and ELECTRICAL FIXED and LOOSE PLANT, MACHINERY, DYNAMOS, MOTORS, ELECTRICAL FITTINGS, GAS ENGINES, PATTERNS, and other effects.

WHEATLEY KIRK, PRICE AND GOULTY are instructed by the Trustee, Arthur Clarke, Esq., TO SELL BY PUBLIC AUCTION, on TUESDAY, the 13th December, 1892, commencing at 10 for 11 o'Clock prompt, the ENTIRE CONTENTS of the EAST DOWN ELECTRICAL WORKS, Dermondy-road, East Down Park, Lewisham, S.E.

Comprising:—8-H.P. Vertical Engine and Boiler, by Davey Paxman and Co.; 6 and 14-H.P. Otto, 2-H.P. Stockport, and 2-H.P. Clark's Gas Engines; Six ¾-H.P. Electrical Motors, Brush, Victoria, Elwell-Parker, E.P.S., Siemens, Gramme, Gills, and Plating Dynamos; 4½in. Stroke Shaping, Horizontal Milling, Planing, Drilling, and other Machines; Fly Presses, Shafting; Six Hand Lathes, 4, 5, and 6in. Centres; 6½in. and 8½in. Slide Surfacing and Screw-cutting Lathes; 46 E.P.S. 23L Accumulator Cells in glass boxes; Switches, ½-H.P. Motors, Valuable Marble Standards, Electroliers, Brackets in brass and hammered-iron Canvas Belting, Loose Tools, Utensils, and other effects.

May be viewed on Monday, December 12th, 1892, and Morning of Sale.

For descriptive Catalogues and any further particulars apply to ARTHUR CLARKE, Esq., Trustee, 6, Lombard-court, E.C., or to WHEATLEY KIRK, PRICE and GOULTY, Electrical and Mechanical Auctioneers, 49, Queen Victoria-street, London, E.C.; And Albert-square, Manchester.

Telegrams: "INDICES," London.

THE METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).

NOTICE is Hereby Given that the coupons due December 1, 1892, on the above-named Company's issue of £50,000 Five per Cent. Registered Debentures WILL BE PAID on and after that date at Messrs. Prescott, Dimsdale, Cave, Tugwell and Co. (Limited), 50, Cornhill, London, E.C., or at the Royal Bank of Scotland, 123, Bishopsgate Within, London, E.C.

Coupons must be left at the Bankers' three clear days for examination.

The REGISTERS of DEBENTURE-HOLDERS WILL BE CLOSED from the 24th to the 30th inst., both days inclusive.

By order, E. CUNLIFFE-OWEN, Secretary.

November 21, 1892.

NOTICE is Hereby Given that the TRANSFER BOOKS and REGISTER of MEMBERS of the ELECTRIC AND GENERAL INVESTMENT COMPANY (Limited) will be CLOSED from the 1st to the 15th day of DECEMBER, 1892, both days inclusive, for the purpose of preparing the warrants for the interim dividend declared on the Ordinary Shares.

By order of the Board, J. CECIL BULL, Secretary.

Offices of the Company: Nos. 1 and 2, Great Winchester-street, London, E.C.

November 22nd, 1892.

SITUATIONS VACANT AND WANTED, &c.

ASSISTANT ELECTRICAL ENGINEER WANTED. Write in first instance, stating experience and salary expected. IMPROVER WANTED. Also VACANCY for a PUPIL.—GILBERT & Co., 35, High-street, Kensington.

MAN WANTED to drive steam-engine and take charge of electric light installation at a private country house, near London: a married man with not more than 2 children preferred; cottage provided, and milk and vegetables found.—Apply by letter, stating experience and wages required, to "W. B.," 179, Piccadilly, W.

ELECTRICIAN (21), 5 years' theoretical and practical experience, Draughtsman, used to test-room work, seeks RE-ENGAGEMENT. Highest referenees. Small salary.—"A. J.," 26, Gower-street, W.C.

YOUNG ELECTRICAL ENGINEER desires APPOINTMENT, home or abroad. Good theoretical training; thorough practical experience in wiring and central station work (high tension); last in experimental department of well-known manufacturing electrical engineers. Could introduce capital. Knowledge of French.—Address, "A. X.," Beal and Son, East-street, Brighton.

PARTNER WANTED by an old-established firm of Merchants, who, having made advantageous arrangements with large Continental Works, are about to add an electric light, &c., department to their business.—Address, "N. T.," care Davies and Co., Advertising Agents, Finch-lane, Cornhill.

WORKING PARTNER WANTED in an old-established, though not extensive electrical engineering business, with £300 to £400 at disposal, to buy out two others (sleeping), and assist advertiser in extending business. Works and offices well fitted, and very conveniently situated; good regular trade.—"X. Y.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

OLD SWAN LAMPS.—WANTED, one of the Old Swan Lamps, with a long neck and cardboard sheath, in good condition.—Apply, stating price, to "S. O. L.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

WANTED, SHUNT WOUND DYNAMO, 120—160 volts, 40—60 amperes. Must be cheap.—T. MARCHANT, 60, Verney-road, S.E.

Penywern House

MILITARY & ENGINEERING COLLEGE,

2, PENYWERN ROAD,

EARL'S COURT, S.W.

Principal: G. W. de TUNZELMANN, B.Sc., M.I.E.E.

Telegrams: "TUNZELMANN LONDON."

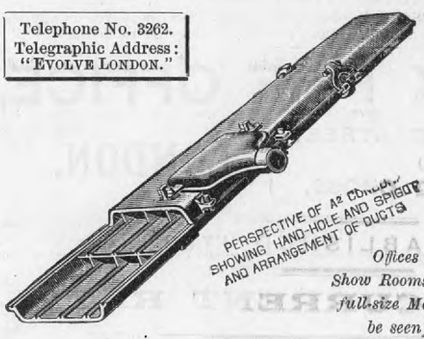
The Complete Courses in the Engineering Department qualify Students for entry into Cooper's Hill, and the Central Institution, Engineering Colleges, and into Engineering Works. Special Courses in Electrical Engineering.

Extensive Laboratories, Dynamo Room, &c.

Students are regularly sent to the College by leading Engineers and Scientific Authorities, whose names are given in the Prospectus.

THE JOHNSTONE SYSTEM OF ELECTRICAL UNDERGROUND CONDUITS.

Telephone No. 3262.
Telegraphic Address: "EVOLVE LONDON."



CABLES ACCESSIBLE AT ANY POINT.

SPECIAL FACILITIES FOR DISTRIBUTION.

Offices and Show Rooms (where full-size Model can be seen):—

WANTED to PURCHASE, several second-hand BRAIDING MACHINES for light work.—THE UNITED ELECTRIC WIRE CO., 14A, Clerkenwell Green.

OLD ESTABLISHED ENGINEERING BUSINESS in YORKSHIRE FOR DISPOSAL under special circumstances. Works and Plant capable of employing 150 hands easily. Bears a high reputation for its products, chiefly heavy engineering tools for British and Foreign Governments, and most of the principal engineering firms. Although a current going concern, an exceptionally low price will be taken. Freehold Land, Buildings, Plant, and Contents under £10,000 for an immediate purchaser.—Apply to WHEATLEY KIRK, PRICE, and GOULTY, 49, Queen Victoria-street, London, E.C.

FOR SALE.—Over 100 ORNAMENTAL IRON STANDARDS, suitable for overhead wiring or street lamp-posts.—Apply EXETER ELECTRIC LIGHT CO. (Limited).

SALE OF PATENT.—The English Patent of an electrical apparatus, affording safety against thieves, burglars, &c., is TO BE SOLD.—Inquire W. RICHTER, Avondale, Batheaston, Bath.

Messrs. WILLIAMS and NORGATE, Importers of Foreign Books, have weekly parcels from the Continent with all the new Scientific Books.

(*Foreign Prices*).

14, HENRIETTA STREET, COVENT GARDEN, LONDON, & 20, S. FREDERICK STREET, EDINBURGH.

FOR VENTILATING AND COOLING ENGINE AND DYNAMO ROOMS,

20 HIGHEST AWARDS, including PARIS, 1889.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 758.—Vol. XXX. FRIDAY, NOVEMBER 25, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

We hear that the action which has been brought against Mr. Graff Baker by the National Telephone Company and arising out of the telephonic disturbances, which the working of the Leeds electric cars is alleged to have caused, will shortly come before the Courts. We trust that electric traction engineers in this country will realise the supreme importance to the future of their industry of a right decision in this action, and that they will not stint their active assistance in aid of the common cause. It was, of course, the bounden duty of the Directors of the National Telephone Company to put this question of "earth" to the test of the law. But sympathy with the victims of the single-wire system does not preclude a desire to see the system itself ended. To string delicate instruments like telephones along "earthed" circuits in a modern city, and then to complain of their being disturbed, seems to us as unreasonable as it would be for an individual with *fin de siècle* nerves to whine about the noise of a busy city into which he had voluntarily thrust himself. We sincerely hope that law and equity will go hand in hand in England as in America.

When we heard in the morning train on Tuesday last that there was nearly a column and a-half in *The Times* on "Wire-to-Wire Electric Lighting," we thought the long-expected revolution had come at last. A Ewing-Parsons generator, a Tesla lamp, and a lampholder so contrived as to raise the frequency to a little more than the cube, and the problem would be solved. Will Mr. Verity or Mr. Binswanger be the first with this lampholder? But in a hasty glance at a poster our fellow-passenger was mistaken, and the discovery proved to be that of "Wire-to-Wire Electric Communication." So much of the information must have been derived from Mr. Preece or from his assistants that it is a pity that the whole of the communication was not written by someone better acquainted with electrical science. Wire-to-wire electric communication means telegraphing without wires. Any electrician can give examples of previous experiments, such as those of the late Mr. Willoughby Smith, which gave rise to some correspondence in our twenty-first volume. Communication has been effected across the Solent, and across rivers in India, while Mr. Preece has made experiments across the Mersey and the Severn, and at several places mentioned in his British Association Paper of 1887, and in yesterday's *Times* Mr. Willoughby S. Smith writes describing a remarkably simple method which has been successfully tried by him off the Needles for the information of the Royal Commission on lighthouse communications.

The problem on which, according to *The Times*, Mr. Preece has been engaged, is electrical communication between the shore and lightships. The three methods which have been proposed are, first, "by running a wire along the shore on light poles for a distance of about a mile, and a second wire from stem to stern of the ship, the two acting upon each other inductively through the intervening space." Why light poles should be used is not evident. We should have thought that along a sea-shore unusually stout poles would have been used, especially as they may be wanted most during a storm. We suppose that ordinary alternating electric currents were used; if so, these wires would probably be earthed at each end, and such effect as was produced might safely be attributed to earth currents.

The second method is "by suspending a short line over the side of the ship, so that it may dip into the sea, in the direction of the end of the shore line, to work by conduction through the sea." We are not told where the other end of this wire goes; perhaps it is screwed firmly into an accumulator in which electric fluid is compressed, and which oozes out at the end. It is thoughtful of Mr. Preece to suggest the proper direction by pointing the free end towards the land line; they do not always take this trouble in liberating carrier pigeons. "And, thirdly, by running out a light cable from the shore to the ship, terminating in a coil at the bottom of the sea, near the ship, but not attached to it, while another coil is placed on board. These two coils are expected to act inductively, and to give ample sound on telephones by means of rapid alternations." This method, we believe, is patented, and very encouraging results on a small scale have been obtained, from which the practical working may be predicted by calculation.

Near Cardiff a shore wire was erected and the lightship was "represented for the occasion by the island of Flat Holme." The line was half a mile long (what a pity the "Great Eastern" is broken up), and was three miles distant. "A powerful generator" was used, and messages were easily sent. "The principle underlying this method is," says *The Times*, "precisely analogous to that which governs the transmission of light itself." And then follows a long account of ether waves, Tesla's experiments, and Prof. Crookes's recent article in the *Fortnightly Review*.

Hosted by Google

The latter part of *The Times' communiqué* refers to receivers accurately timed to respond to vibrations of a definite period, but the statement that the connection is made "only by the ether which occupies interstellar space" does not explain whether Hertzian oscillations or ordinary electric currents are used. In the early part of the article alternating currents are mentioned, and the effect, it is said, appears to depend principally upon the distance which separates the two wires. It would have added a scientific flavour if "the square of the distance" could have been brought in without materially interfering with the accuracy of the statement. When the time comes for Mr. Preece to describe his experiments with his usual lucidity, the confusion and ambiguity of this preliminary bit of newspaper science will matter little.

In our Note on the Regent-street fire last week we remarked that our inquiries on the spot had failed to elicit anything in support of the suggestion that the fire was due to electrical causes, but we did not go so far as to state, as Mr. Human suggests in his letter (which will be found in our Correspondence Columns), that the "fire was in nowise connected with the electric installation." We thought it worth while to remark that no evidence had been elicited, since it is to be presumed that Capt. Simmonds had some good grounds for distinctly attributing the fire to electrical causes. If it is the intention of this officer to report that fires are due to "overheat of electric wires" instead of "cause of fire unknown, but premises were fitted with electric light," the sooner the value of these reports is known the better. The utility of such reports would seem to be in proportion to the trouble involved in their preparation. As it is, one large firm of contractors, who are in no way connected with this case, have informed us that this unusual accident, or rather this very unusual report, has distinctly injured their business.

Mr. Human's hypotheses, on the other hand, are worthy of very careful consideration. He puts his arguments very clearly, and his assumptions require, as he says, no great stretch of imagination. We are quite disposed to agree with him that it is time to reconsider the position. We have hitherto refrained from advocating the earthing of the middle wire, because several leading engineers have thought that the time had not yet come for fighting for it. We suppose there will be a fight. It has begun in New York. The Edison Company have earthed their "middle" in a most determined manner, but they have only the insurance offices and a political hybrid, called the Board of Electric Control, against them, and know not what it is to have a Board of Trade. If we understand the present opinion of the Board of Trade, it is this: Take plenty of insulation. Insulation is good, more insulation is better, and so of course the most insulation is the best. This contention, backed by a committee whose constitution may be called an exaggeration of that of the Council recently under discussion, produced the overhead wire rules, and by the same contention the middle wire is, of course, to be insulated. When at last an accident occurs—and we do not admit that this has yet arrived—it will of course be easy to say, "You had not enough insulation. Take plenty of insulation."

While allowing this important question to develop by degrees, we have reproduced in our columns several noteworthy articles which have appeared in foreign journals, but have not commented upon them. Mr. Human's letter compels us to say a word or two, and to do this nothing more is needed than to slightly amplify parts of his communication. Leaks have arisen and must arise *on one pole or the other* of supply companies' mains. To use double-pole switches invariably, is only to introduce complications and risks which are inseparable from such devices when made on a small scale. If a leak is started on one of the street mains, the Company alone, and not the consumers, should be inconvenienced thereby. It is to be presumed that the "middle" would be earthed through an ammeter, and, as a matter of fact, one company, in an unofficial, private, and altogether experimental manner, has thus occasionally used a recording instrument; with an absolutely negative, that is to say, the best possible result. If a leak arises on the "middle," the engineer will discover it in due time, but meanwhile no harm will be done; if it occurs on an "outer," he will be obliged to repair it at once by stress of circumstances which at present have no existence. To those who have not yet given attention to this extremely important matter we recommend a study of Mr. Human's diagram, and of this simple means for providing against the possibility of an accident.

Several of the London Companies who work the direct low-pressure system are congratulating themselves on the great reductions that have been made during the current year in working costs. It is an open secret that a friendly rivalry in economy of working exists between several of these Companies. We hear that in the month of October one of the stations of the Kensington and Knightsbridge Company has beaten the record, the total cost of grinding out the current, to use Mr. Justice A. L. Smith's expression, having been only 1·173d. per supply unit sold to the customer, the coal used being 5·9 lbs. per unit generated, or 6·4 lbs. per unit sold. We hear that the month of November will show still better results, not only in this but in several other stations, notably at some of those belonging to the Westminster Company, where the condensing plant has been recently got to work. We have no information as to the cost per unit at Westminster, but we understand that at Eccleston-place, where they were condensing every day during the heavy watch, the last week's coal account worked out at 5·31 lbs. per unit generated, and 6·23 lbs. per unit delivered to consumers.

Competition is the salt of business; and when the weak are driven to the wall they become socialists and deprecate the battle being for the strong. But to some forms of competition the most brangling demagogue can hardly object, even on what he is pleased to call principle. The Westminster Electric Supply Corporation has its three stations in parallel, and unless we are mistaken there is considerable friendly rivalry between the engineers in charge, as each one wishes to get as large an output as possible. A small difference in pressure at certain feeding points has been found to make a considerable difference in the area which each station supplies.

Hosted by Google

Hence we believe occasional complaints and expostulations through the telephone as to the poaching tendencies which each gentleman thinks to be manifested by his colleagues. As a matter of fact it is arranged that, as far as possible, the light load in the day-time shall be taken by Eccleston-place, which is midway between the other two stations. Another, but an incorrect version of the story, is that one engineer kept his pressure a volt or so lower, thus allowing the other stations to supply his district and enable him to boast of a small coal bill.

Beckenham.—The Local Board have decided to apply for an Electric Lighting Order.

Reading.—The Reading Electric Supply Company are applying for an Electric Lighting Order.

Royal Society.—None of the medals of the Royal Society are this year awarded for electrical research.

Inter-urban Telephony.—A telephone trunk wire is to be established between Berlin and Posen, a distance of 170 miles.

The Cheesbrough Patent.—The Cheesbrough (Sawyer-Man) Patent, No. 4,847, of November 28, 1878, expires on Monday next.

Electric Traction in Germany.—A concession has been obtained for the construction of an electric tramway between Altona and Blankenese.

Newington Vestry.—This Vestry has decided to oppose the application of the County of London Electric Lighting Company for a Provisional Order.

Electricity in Mines.—The Marien coal mines in Saxony have recently been provided with an electric power plant by Schuckert and Co., of Nuremberg.

Chagford (Devon).—The streets of this enterprising little town, which has adopted "Hedgehog" transformers and other novelties, are now illuminated with the electric light.

Gibraltar.—The permission for raising a loan not exceeding 900,000 pesetas (about £34,000) for the supply of electricity for lighting and other purposes in Gibraltar has been obtained.

Perth (Western Australia).—The city of Perth (Western Australia) is being canvassed by an electric light company. As gas is 15s. a thousand, the B.T.U. even at 1s. would be a boon.

Proposed Electric Lighting Legislation in Canada.—A Bill is being drafted providing for Government inspection of electric lighting and is to be introduced during the next Session of Parliament.

Post-Office Appointments.—Mr. W. H. Preece, F.R.S., Assistant Engineer-in-Chief and Electrician, to be Engineer-in-Chief and Electrician.——Mr. J. Hookey, Principal Technical Officer, to be Assistant Engineer-in-Chief.

The Blackpool Electric Tramway.—The Town Council have decided to extend the electric tramway to the South Shore. A company is being formed to construct a similar system of tramways between South Shore, St. Annes, and Lytham.

Glasgow.—The electric light works are now going steadily forward. As at present arranged there are to be 106 electric lamps, which, at £20 each, will cost the Lighting Committee some £2,120 annually. The lamps are about 20ft. high.

The late Prof. Dittmar.—A Civil List pension of £75 per annum has been granted to Mrs. Dittmar, widow of the late Prof. William Dittmar, Professor of Chemistry in Anderson's College, Glasgow, in consideration of the distinguished services of her husband.

Paris.—M. E. L. Naze, concessionnaire for the electric lighting on the left bank of the Seine, has deposited the 300,000fr. caution money required by the Municipality, and obtained the necessary capital for carrying out the scheme. Work will be shortly begun.

Lisbon.—In consequence of an accident to the electric lighting at the Opera House, where there is no other means of illumination, the gala performance on Sunday night last in honour of the return of the King and Queen of Portugal from Spain was suspended.

Telephone Wires.—Some telephone wires having been fixed to the steeple of the Church of St. Martin's-in-the-Fields, Trafalgar-square, which is just now undergoing repair, the churchwardens have given formal notice that unless they are removed within a month they will be cut.

The Pacific Cable Scheme.—A Reuter cablegram from Ottawa says that a deputation of influential members of the Ottawa Chamber of Commerce had an interview on Tuesday with a representative of the Canadian Ministry, at which they requested the Government to urge the Imperial authorities to aid the Pacific cable scheme.

The Carnaby-street Station.—At ten o'clock on Friday night last week several calls reached the fire brigade stations for Carnaby-street, Golden-square, where the basement of the premises of the St. James's Company was on fire. Several engines were despatched, and the mischief was restricted to the portion of the premises in which it had originated.

Cable Interruptions.—

Cable.	Date of interruption.
Bolama-Bissao (communication with)	September 9, 1892
Cayenne-Vizeu	September 24, 1892
Para-Maranham.....	October 15, 1892
Ceara-Maranham	November 9, 1892
St. Thome-Loanda.....	November 24, 1892

Société Internationale des Électriciens.—At the meeting of this Society, on the 2nd inst., M. Mascart announced that subscriptions to the amount of 100,000fr. had been received by him towards the new laboratory. In addition MM. Weyher et Richemond had promised a 25-H.P. engine, and M. A. Hillairet had undertaken to supply all the mechanical appliances.

Proposed Electric Cars at Coventry.—The independent deputation of members of the Coventry City Council who left Coventry on Wednesday night last week for Leeds, for the purpose of inspecting the electric traction in use there, have returned with their views very much modified as to the objections, and with a favourable impression as to the advantages of the system.

Finding Faults in Coils.—The Thomson-Houston Company test the insulation of all coils turned out at their Lynn factory by placing them in a powerful alternating magnetic field. The circuit being open there will be no appreciable heating; should a short circuit, however, exist anywhere a heavy current will be generated, and the bobbin will soon become perceptibly warm.

The Merchant Venturers' School.—In view of the large increase in the mechanical and electrical engineering departments of the Merchant Venturers' School the governors have invited Sir J. Fowler to distribute the prizes and medals, and to deliver an address to the students in the departments of science, art, and technology. Sir John has consented to visit the school for this purpose on Thursday, December 8th.

Electric Traction in Germany.—The Bremen overhead trolley line has at present about four miles of road, and it is now proposed to extend it. The number of passengers carried has risen 30 per cent. in the past year.——The Allgemeine Elektricitäts-Gesellschaft are making rapid progress with the Breslau tramway, which is also on the overhead trolley system; about five miles of underground conductor are now laid.

Worcester.—On Friday last, at the meeting of the Watch Committee, it was resolved to recommend the City Council to purchase Powick Mills, on the River Teme, for the purpose of electric lighting, at a cost of £5,000, and to accept an alternative tender by the Brush Company amounting to £23,209. It was stated that by utilising the water power of the Teme for generating the electricity a saving of £1,416 per annum would be made.

The Proposed International Electrical Exhibition in Milan. With regard to this proposed Exhibition in 1894, the Committee are now proposing to offer, in addition to the usual diplomas and medals, a "grand premium" for the most important invention and discovery in the field of electricity, having special regard to the long distance transmission of

Hosted by Google

electric energy, and its distribution and transformation for industrial uses.

Cork.—At the last meeting of the Town Council the recommendation of the Special Committee *re* electric light, Oct. 4th: "That the Council refuse its consent to the application of the Cork Gas Consumers' Company for a Provisional Order to enable them to supply electrical energy within the borough; and that should the Company persist in such application, the Council on its own part to apply for a Provisional Order for the same purpose," was deferred for a month.

Proposed Electric Railway from Victoria to Kilburn.—During the ensuing Session of Parliament a Bill is to be promoted with the object of incorporating a Company for the purpose of constructing an underground electric railway from a point on the Vauxhall Bridge-road side of Victoria Railway Station, and passing from thence under Edgware-road to Kilburn. The gauge which it is proposed to adopt on this line will be the ordinary standard gauge adopted on all passenger railways of 4ft. 8½in.

The South Staffordshire Electric Cars.—In view of the success of the electric cars on the South Staffordshire lines, the Chairman of the Birmingham Central Tramways Company, it is stated, thinks it prudent to keep an open mind as to the advisability of using electric instead of cable traction. If overhead wires were permitted, the Central Tramways would, he believes, prove "a gold mine." The Mayor and Corporation of Birmingham are to be invited to visit Darleston for the purpose of inspecting the electric cars.

Lord Kelvin's New Form of Electrostatic Voltmeter for Low Voltages.—The arrangement of the vanes and cells of this instrument are much the same as those of the multicellular voltmeter already described in these columns. The instrument is specially designed for use on switchboards, and has a vertical scale instead of the old plan of reading with a mirror. It is rendered practically dead beat in its action by a small horizontal disc which turns in an oil dashpot below the case. The zero adjustment has been modified by the addition of a torsion head and micrometer screw.

Naval Signalling.—*The Times* states that the battleship "Anson" is to be supplied with the new pattern electric flashing signal lamps on her return to Devonport. Six of these lamps have been ordered for trial in the Mediterranean Squadron, and the "Royal Sovereign" has also been supplied with one. So far the lamp has been unfavourably reported upon. It has been found that flashes cannot be made with the necessary rapidity owing to the fact that light lingers in the carbon. The lamps are of about 100 c.p., and are worked at the masthead by electric wires from the deck.

Coast Communication.—The islands of Scilly, Tresco, Bryer St. Martin's, St. Mary's, and St. Agnes, are now telephonically connected, and the coastguard station at Porthleven has been connected by telephone with the Lizard signal station, a distance of 14 miles, and from the signal station a wire has been carried to the chief officer of coastguard two miles away. There is a wire from the Lizard station to Cadgwith post-office and the Cadgwith coastguard. It is expected that shortly all the lighthouses around the coast, including the Wolf, Longships, Bishops, and St. Agnes, will be connected with one or other of the various circuits.

Hove.—On Saturday last the new supply station at Hove was started, only 90 days after the signing of the contract. The mains were laid and closed in in 60 days, and on the opening day some 1,300 lamps were connected, thus ensuring an income of some £700 or £800 per annum from the commencement. Hove being practically part of Brighton, this town now possesses no less than three systems of electric lighting. The Hove Commissioners have granted the concession to the Hove Electric Lighting Company (Limited) for 42 years. We understand that much of the credit of this smart bit of work is due to Mr. Stevenson, the resident engineer and representative of Messrs. Crompton and Co., who have secured the contract for the whole of the works.

Larne.—A specially-convened meeting of the Town Commissioners was held on Monday evening last. Mr. M'Williams said there had been a good deal of time lost at that Board over the question of electric light. They had been informed repeatedly that the contractors were doing their best to make the light a success, and he believed they were, but so far they had failed to make the light what they all would have desired to see. He would propose:—"That a letter be sent as final to Messrs. Gordon and Co., stating that the present lighting of the town was not by any means satisfactory, and that the Commissioners will not pay for light not received by them, and will deduct what they may consider fair and just out of their account for supplying electric light in future." The motion was passed, all voting in its favour except one member.

The City Lighting.—At Tuesday's meeting of the City Commission of Sewers a letter was received from the City of London Electric Lighting Company relative to the progress made. They stated that out of 515 arc lamps contracted for in the principal streets, 409 had been supplied, some of them three months before the contract time. Of the remainder, the positions of 44 had not yet been definitely fixed, but the list would be completed as soon as the operations retarding them, and for which they were not responsible, such as the repaving of streets, were finished. They were now prepared to go on with the erection of the incandescent lamps in the smaller streets. Mr. Malthouse said the work had been very well done, and speaking from his experience at the Central Markets, the lighting of the City, as experienced during the recent fogs, was a great improvement on gas. Mr. C. T. Harris raised the question whether the Court had ever given the Company power to light the less important streets with incandescent lamps. He contended that this method of lighting was most costly and extravagant, and was equivalent to using perfumed water to turn a mill.

Imperial Institute.—Sir Frederick Abel having acted as proposer to the whole body of Civil Engineers, Mr. Preece is doing the same for the Electrical Engineers. The first privilege set forth in a circular which has been sent to all members and associates of the Institution, is that of attaching "the distinctive designation of 'F.I.Inst.'" after the name of each Fellow. We have recently visited the Institute, under a guidance of a Fellow who was compelled to show a ticket of membership on entering. We understand that the Library is not yet built; the News-Room is well supplied with daily papers, but the Reading-Room has a very scanty selection of magazines and periodicals, besides those connected with trades and Colonial commerce, while the Refreshment Department is arranged in the style of a public refreshment-room at a museum or railway station. The telephone is fixed in one of the offices, and conversation has to be carried on in the presence of a number of clerks. As an Imperial Institute the place may no doubt be well arranged, but it is fair to warn intending Fellows that they must not expect to find the conveniences of a club in the building as at present arranged.

Exports of Telegraphic Apparatus.—The Board of Trade returns are again unsatisfactory so far as regards our exports of telegraphic wiires and apparatus connected therewith. The exports for October were again much below those for the corresponding month last year or the year before, having amounted in the aggregate to but little over £31,000. In April last the value of our exports under this head reached the very large total of nearly £448,000, and had it not been for this exceptionally large movement, the aggregate figures would have been very much worse than they are. As it is, our total exports for the first ten months of the current year are less in value than two-thirds of the exports in the corresponding period of last year. Below we give a statement of the exports for the first three quarters and for last month, in comparison with the corresponding figures, for 1891 and 1890:—

	1890.	1891.	1892.
First Quarter.....	£324,670	£653,081	£96,079
Second Quarter	397,042	331,449	579,756
Third Quarter.....	210,280	342,106	124,605
Nine Nonths	931,992	1,326,636	800,440
October.....	335,064	38,167	31,198
Total ten months...	£1,267,056	£1,364,803	£831,638

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 16.)

21. The Cable Ships "Store Nordiske" and "H. C. Oersted."—These two vessels, although belonging to one Company—the Great Northern Telegraph Company—are at work on very nearly opposite sides of the globe. The two portions of this Company's submarine system are situated in the waters of the Far East and northern Europe respectively. The "Store Nordiske" presides over the cables in the Far East, numbering nine in all, or thirteen if counted by sections, besides those of the Japanese Government. These cables principally connect Northern China, Japan, and Corea with the town of Wladiwostok on the eastern littoral of Russian Asia. From this town the great Russian land-line system of 9,000 miles spans the continent of Asia, and communicates with St. Petersburg and the Baltic Sea coast. Thence follows the European cable system of the above Company, connecting Russia with Germany, Sweden, Norway, Denmark, France, and Great Britain, and numbering in all 12 cables in 16 sections. This latter system, running through the North and Baltic Seas, is kept in repair by the steamer "H. C. Oersted." The faults repaired by this vessel in cables crossing the North Sea between Scotland, Norway, Denmark, and Newcastle, are chiefly caused by trawlers in the North Sea fishing fleets. At Shanghai the Eastern Extension Company's system joins that of the Northern Company, and connects China with Australia, India, Africa, and Europe.

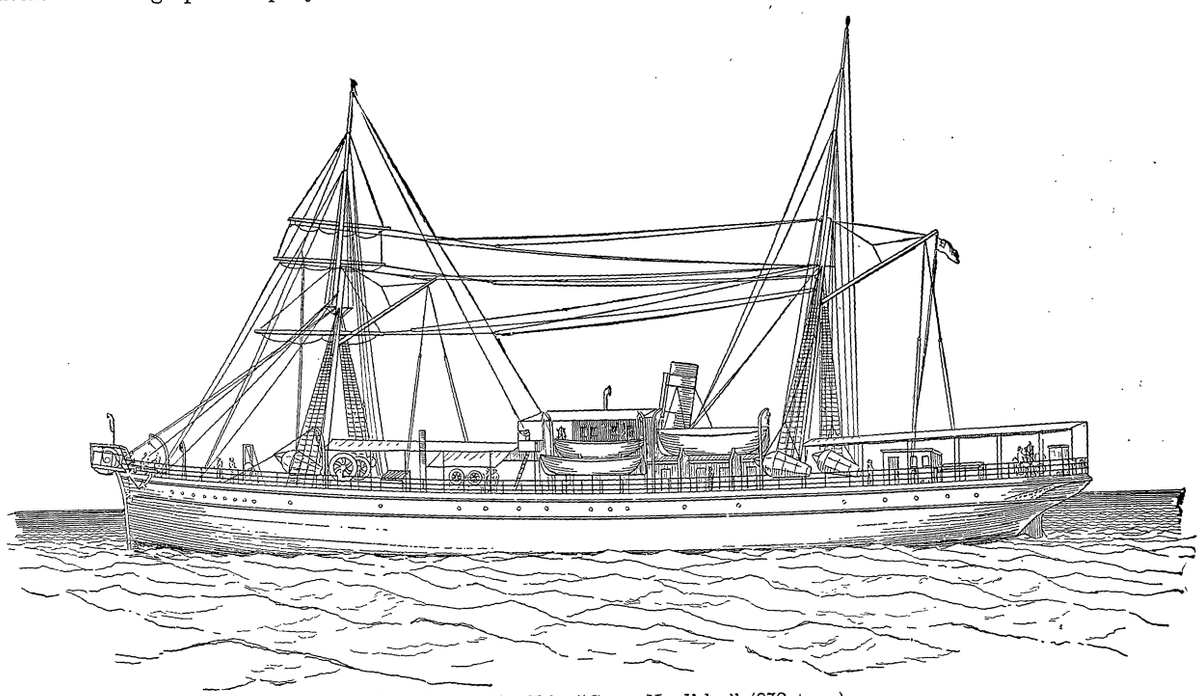

FIG. 78.—Cable Ship "Store Nordiske" (832 tons.)

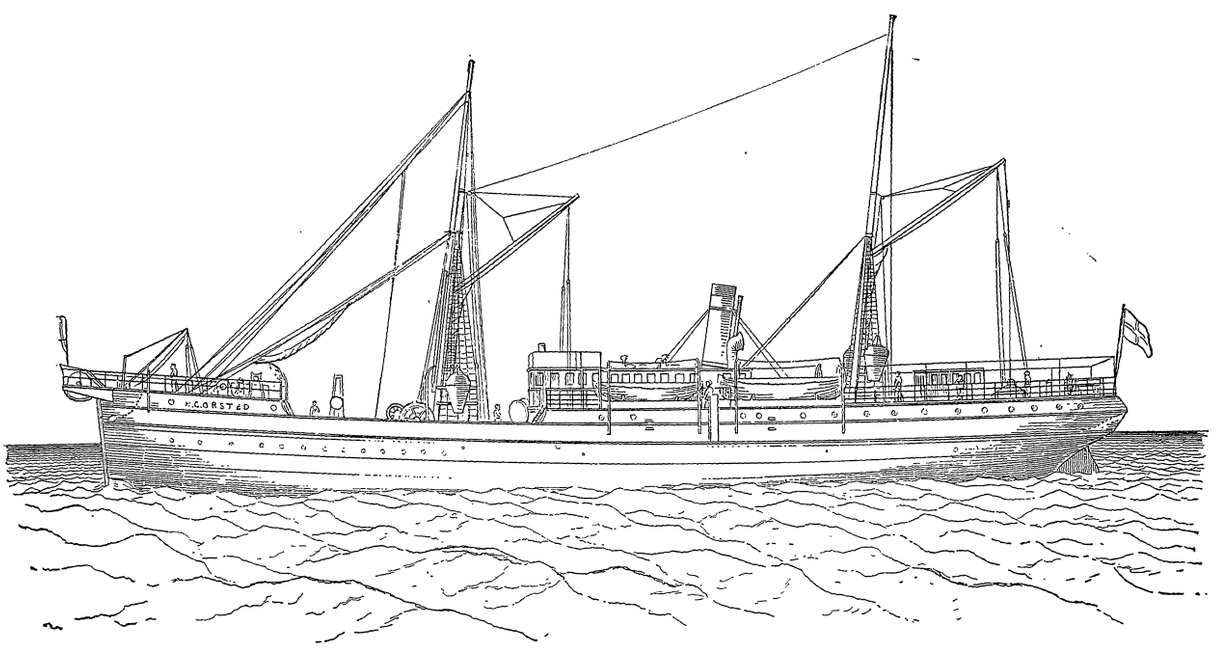

FIG. 79.—Cable Ship "H. C. Oersted" (750 tons.)

The illustrations of these vessels (Figs. 78 and 79) are from photographs kindly lent to the writer by the Great Northern Company, that of the "Store Nordiske" being a very good one, taken at Shanghai by a shrewd John Chinaman. It will be noticed that these vessels are of very compact form, light

tonnage, and carry no gear aft, being specially fitted for repairing work, all operations being carried out from the bows. The sets of steam gear for picking up and paying out were fitted on these vessels about 11 years ago by the Thames Ironworks Company, to the designs of Mr. W. B. Esson, well known for his more recent contributions to the theory of dynamo design. In Fig. 80 is shown the arrangement of this gear as fitted on board the "Store Nordiske." Steam is delivered to two inclined cylinders with trunk action, driving direct on to pin of crank-disc A. Between this shaft and that of the winding drum there is a second motion shaft driven by spur-gearing, which reduces the speed between the drum and engine shafts in the ratio of 5 to 1. The illustration being a sectional elevation does not take in the drum, but it may be remarked that the large spur-wheel on drum shaft is made fast to the drum itself, the latter having arms and a boss to key on shaft, and the spur-wheel being made up in segments bolted to the internal flange of drum. With this arrangement no strain is put upon the spokes of the drum or spur-wheel, as is the case when the latter is built as a separate wheel, and keyed to the shaft at a little distance from the drum. When so built the strain comes on the spokes and keys, and a torsional strain is put on the shaft, which is avoided by making the wheel one with the drum. As far back as 1863 Mr. F. C. Webb made this improvement in the gear he designed for the cable-ship "Amberwitch," the repairing vessel for the Persian Gulf cables. The brake on main brake wheel B can be set up by weighting the lever S. The hauling-off pulley H is mounted on a separate shaft with clutch and lever for throwing in or out of gear. With the clutch over to one side the pulley is set in motion at a circumferential speed a little in excess of that of the drum, so pulling cable taut away from the latter, as required during picking up. Putting the clutch over to the other side disconnects the shaft from the driving pulley, and couples it to a small brake, E, the tension on which can be adjusted by the lever O to keep cable taut on its way to the drum from the tank, as required in paying out.

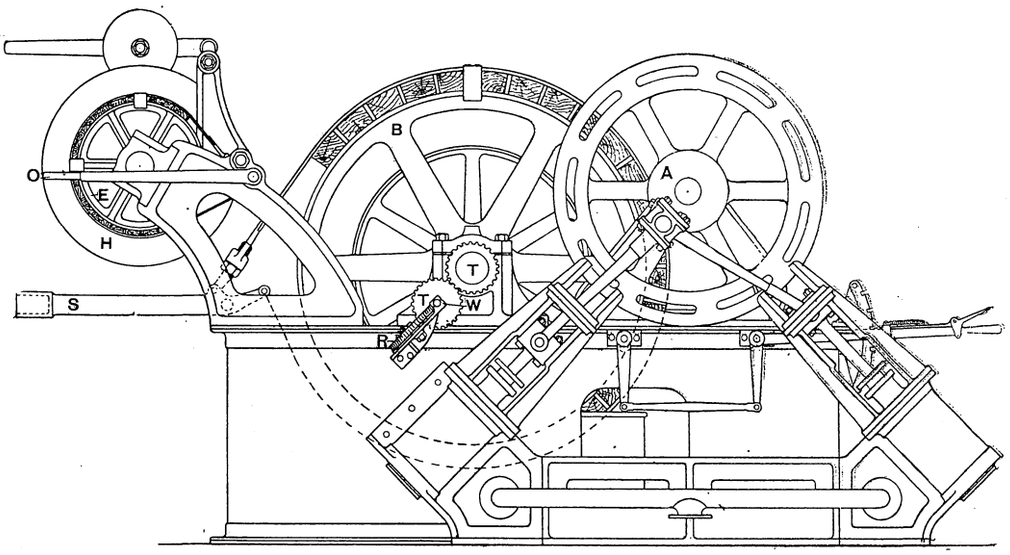

FIG. 80.—Elevation of Cable Gear.

Driven off the drum shaft through the intermediary of the toothed wheels T T, and worm on shaft W, is a very simple form of rotometer for recording the number of revolutions made. The dial R, graduated in revolutions of the drum, is slowly rotated by the action of the worm on its outer circumference, the index hand remaining stationary, and being set to zero at starting. This is read very easily, and there is nothing to get out of order, while, like all rotometers which follow both the forward and backward movements of the drum, it registers the exact length of cable passing between bows and tank during picking up or paying out without calculation.

Two knives for fleeting the turns of cable on drum are fitted on opposite sides of the drum, the forward one for use in picking up, and the other behind for paying out. The former is made moveable as shown, so that when it is required to remove the turns of cable bodily off the drum this knife can be shifted out of the way. This is frequently a necessary operation where there is only one drum as in this set of gear. When the ship, engaged in paying out cable after removal of fault, arrives at the buoy, the drum is required for picking up the buoyed end and consequently the turns of cable then on the drum have to be removed bodily. The cable is therefore stoppered at the bows, first taking off all strain from the drum, then the fleeting knife is moved out the way and the turns of cable slipped off. As picking up proceeds on the buoyed end the ship moves forward a little, and the stoppers on the payed-out end are eased to allow cable to slip through as required. The only objection to this is that the amount of cable so payed out by hand is not measured, or only approximately so. In the first ten years of cable gear construction drums were made with outside bearings so that cable could not be got off without cutting it, and this involved much inconvenience and waste in wrongly judging length at which to cut. The first overhanging drum was constructed by Mr. Webb on the vessel above alluded to in the year 1863, and has since been universally adopted.

22. Regulations Affecting Cable Ships at Sea.—Cable ships engaged in picking up or paying out cable cannot get out of the way of other vessels that may be approaching them, and therefore, in order to prevent collisions, the Admiralty, in conjunction with the Board of Trade, drew up some special rules to be observed by British cable ships when so engaged. These rules were included in the "Regulations for Preventing Collisions at Sea," issued in pursuance of the Merchant Shipping Act Amendment Act of 1862, and were confirmed by an Order in Council of August 11, 1884. In framing these rules it was recognised at the outset that a cable ship engaged in laying or picking up cable at sea was in the same condition as a disabled steamer, inasmuch as she could not get out of the way of other ships in her neighbourhood, and that, therefore, she should fly signals of a similar character. A disabled steamer is required to carry by night three red lights on the foremast head in place of the usual white light, and by day three black balls or shapes, all in a vertical line. If, however, the signals carried by a cable ship were exactly like those of a disabled steamer, passing vessels would bear down upon her to render assistance, and therefore some distinguishing signal was necessary. This was effected as regards night signals by making the centre light of the three a white light, and by day flying red globular shapes at top and bottom with a white diamond-shape between them.

The full text of the three clauses in Article 5 of the "Regulations" is as follows :—

(*b.*) A ship, whether a steam ship or a sailing ship, employed in laying or in picking up a telegraph cable, shall at night carry in the same position as the white light which steam ships

Hosted by Google

are required to carry, and, if a steam ship, in place of that light, three lights in globular lanterns each not less than 10in. in diameter, in a vertical line over one another, not less than 6ft. apart; the highest and lowest of these lights shall be red, and the middle light shall be white, and they shall be of such a character that the red lights shall be visible at the same distance as the white light. By day she shall carry, in a vertical line, one over the other, not less than 6ft. apart, in front of but not lower than her foremast head, three shapes, not less than 2ft. in diameter, of which the top and bottom shall be globular in shape and red in colour, and the middle one diamond in shape and white.

(*c.*) The ships referred to in this article, when not making any way through the water, shall not carry the side lights, but when making way shall carry them.

(*d.*) The lights and shapes required to be shown by this Article are to be taken by other ships as signals that the ship showing them is not under command, and cannot, therefore, get out of the way.

(*To be continued.*)

OPEN AND CLOSED MAGNETIC CIRCUIT TRANSFORMERS.

BY W. E. AYRTON AND W. E. SUMPNER.

In a Paper read before the British Association on August 5, 1892, and reprinted in *The Electrician* for October 7th, we described a number of tests made to determine the losses occurring in transformers of the closed circuit type under ordinary working conditions. The tests actually published referred to four Mordey transformers of outputs varying from 1·5 to 4·5 kilowatts, but it was stated that numerous experiments had been made on a Hedgehog transformer of 4 kilowatts output, and that these tests showed that neither at no load nor at full load was there any great difference between the power wasted in a Hedgehog and in a Mordey type of transformer of the same output. The details of the tests on the Hedgehog transformer were, however, reserved for later publication, as it seemed desirable to analyse more fully some of the results obtained.

Since that date we have repeated the tests, and by using a slight modification of the method before employed (*see* Fig. 1, p. 615, *The Electrician* for October 7, 1892) have obtained very satisfactory results. As we indicated in the Paper already mentioned, some of the peculiar results previously obtained with the Swinburne transformer were due to its large magnetising current, which prevented the current, as read by the dynamometer, being any measure of the load on the transformers. Corrections had also to be applied owing to the fact that the transformers were working at somewhat different voltages.

The arrangement of the apparatus employed for the recent tests is shown in the figure. The thick coils of a three-kilowatt Mordey transformer M, and of a four-kilowatt Hedgehog transformer H, were put in parallel on low-pressure mains, a Siemen's dynamometer S D being so connected as to measure the current through the coils of H. A Ganz wattmeter G W measured the power supplied to the combination of M and H. A third transformer T had its primary on the mains, and its secondary in series with the fine coils of M and H, these latter coils being connected so that their voltages opposed each other. A Swinburne wattmeter S W measured the power given out by the secondary of T, and an Ayrton and Mather electrostatic voltmeter V was arranged to measure the voltage on the fine coil of either H or M. In all the tests the fine coil of H was adjusted to 2,000 volts, and the transformer T was so arranged that H transformed down. In some of the tests a reflecting dynamometer, measuring up to two amperes, was placed fn the high-pressure circuit, in which case the dynamometer S D was dispensed with. The sum of the readings of the two wattmeters measured the total power wasted in M and H, and, as the losses in M were known from the previous tests for all frequencies, voltages and currents, those in H could be found.

In testing with alternate currents it is most necessary to ensure that the currents in the leads do not affect the readings of the dynamometers and wattmeters employed. The only effectual way of doing this is to twist together the two wires which lead up to and away from each instrument. Moreover, as suggested by us in connection with Mr. Swinburne's Paper on "Electrical Measuring Instruments," read in April last at the Institution of Civil Engineers, it is of particular importance in testing *open* magnetic circuit transformers to take great care that the stray alternating field does not act directly on the measuring instruments. To make sure of this we have found it necessary to place the measuring instruments several yards away from the Hedgehog transformer.

The following is a sample of tests made at a frequency of 100 ∿, with the dynamometer in the fine-wire circuit :—

Volts in Hedgehog transformer	2,000	2,000	2,000	2,000
Volts in Mordey transformer	2,000	1,960	1,950	1,880
Amperes in fine-wire circuit	0	1·32	1·53	1·84
Sum of watts read by two wattmeters	275·0	339·5	362·5	391·5
Watts lost in coils of Mordey transformer	0	40	54	78
Watts lost in iron of Mordey transformer	106·5	105·5	105·0	96·0
Watts lost in copper and iron of Hedgehog transformer	168·5	194·5	203·5	217·5
Watts lost in copper of Hedgehog transformer	0	28·2	39·5	55·0
Watts lost in iron of Hedgehog transformer.	168·5	166·3	164·0	159·5

For convenience of tabulating, the numbers under the head of copper losses do not include the constant part of the copper losses, viz., that due to the magnetising currents, and this latter is included in the numbers under the head of iron losses. The watts lost in the iron of the Mordey transformer diminish as the load is increased owing to the fact that the voltage at which it is worked diminishes as the current increases, the alteration being shown by the numbers in the second row of figures.

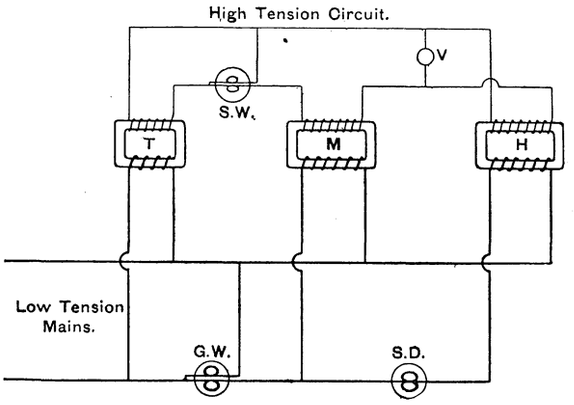

Diagram of Connections.

Shortly before these tests were made the Ganz wattmeter was tested to see whether it read correctly. The open-circuit losses of M and H were tested separately, and were, respectively, 105 and 163 watts. The sum of the two losses was also tested and found 271, which is sufficiently near 268, the sum of 105 and 163, to show that the inductive nature of the load introduced no appreciable error in the wattmeter readings.

The losses occurring in coils of the Hedgehog transformer were tested with both direct and alternating currents, and found to be 65 watts at 40 amperes.

Complete sets of experiments were made not only at frequencies of 100 ∿, but also at 150 ∿ and 200 ∿. It will be sufficient, however, to add a sample of the results at a frequency of 200 ∿.

Volts on Hedgehog transformer	2,000	2,000	2,000	2,000	2,000	2,000
Volts on Mordey transformer	2,000	1,820	1,775	1,695	1,645	1,600
Amperes in thick-wire circuit	0	19·2	20·35	24·10	25·6	28·1
Sum of watts read by two wattmeters	192	234	228·2	241·0	256·0	270·0
Total copper losses in watts...	0	41·3	46·5	65	73·5	88·5
Total iron losses	192	192·7	181·7	176	182·5	181·5
Watts lost in iron of Mordey transformer	80	73	71	68	66	64
Watts lost in iron of Hedgehog transformer	112	119·7	110·7	108	106·5	107·5

Hosted by Google

The open-circuit losses at different frequencies were also separately determined, and the mean of a large number of tests gave the following numbers for the Hedgehog transformer :—

160 watts	at a frequency of	100 ∿
131 „	„ „	150 ∿
117 „	„ „	200 ∿

and these numbers, when expressed as a fraction of the full load of 4,000 watts, give 4·0 per cent., 3·27 per cent., and 2·92 per cent. Whereas, as stated in our British Association Paper, the open circuit losses for a transformer of the Mordey type, expressed at a fraction of full load, were only 3·2 per cent., 2·8 per cent., and 2·36 per cent., at frequencies of 100, 120, and 160 ∿ , and, of course, still less at a frequency of 200 ∿ .

From the results given in this communication, we obtain as the efficiencies of the Hedgehog transformer at the full load of 4,000 watts, 94·38 per cent., 95·10 per cent., and 95·45 per cent., at frequencies of 100, 150, and 200 ∿ respectively.

ON THE POSSIBLE OCCURRENCE OF TORSION CURRENTS IN THE CORES OF TRANSFORMERS.

BY FRED. T. TROUTON, M.A., SC.D.

At the British Association last year I described some rather peculiar results I had then obtained while endeavouring to experimentally investigate the rate of propagation of magnetic disturbances in iron.*

An interference method was adopted in these experiments. A large iron ring (about 12ft. in circumference) made of iron wires had placed on it a coil through which alternating currents were sent. There was a second coil on the ring connected with a telephone which could be moved round the ring. The experiments were intended to ascertain if, at very high rates of alternation, the waves of magnetism sent round the ring in opposite directions would interfere and produce places of silence, and these were to be observed by means of the telephone.

Places of silence or nodes were found to occur round the further half of the ring from the alternating coil, provided the alternating coil was placed in certain positions. Each of these latter positions lay between places where nodes were to be found for some other position of the alternating coil. The nodes on the whole were at nearly equal distances apart, but did not alter their position with the rate of alternation, thus precluding all idea of wave interference. Yet, in spite of this, it was found that the vibrations on either side of a node were in opposite phases, as they should be, supposing the phenomenon due to stationary waves, produced by interference as in an organ pipe. This was ascertained by employing two coils connected in series with the telephone. On placing them at equal distances to either side of a node the induction currents interfered and produced silence in the telephone.

After much investigating it was found that this phenomenon, which in such a remarkable manner simulated a magnetic wave interference effect, was due not to any magnetic effect at all, but was due to the iron being in some peculiar state at certain places round the ring, which, when the alternating coil was at one of them, caused a current to flow in the iron at *right angles* to the plane of the inducing alternating coil. And then again it was due also to this current flowing round the ring and in converse order inducing currents at *right angles* to its own direction in the coil connected with the telephone, provided it also was placed at positions on the ring in this peculiar state, between these positions the nodes occur. Further, it was found that this peculiar state was due to twisting of the iron of the ring, which resulted from the tendency a large coil rewound from a smaller one has to twist up into fairly regular lengths, succeeding sections of which are twisted in opposite directions. These lengths are separated by portions of untwisted iron. When special precautions were taken in making a ring to prevent this twisting it was found that the phenomenon did not occur.

* *Electrician*, Vol. XXVII., p. 520.

Direct experiments were undertaken with the view of further investigating this subject. An alternating coil was placed on a rod of iron, to the ends of which a telephone was connected up, or conversely the alternating current was passed through the rod while the telephone was connected with the coil. In both cases, if a permanent twist had been given to the bar, induced currents were evinced by sound in the telephone. The relative direction of these induced currents depended on the sign of the twist given. Subsequently to this I learnt that Prof. Hughes had some years since, in connection with the Inductive Balance, most completely investigated these effects produced through twist in iron.*

Most of the specimens of iron I experimented with were found, even while in the original state, to be in a condition to afford, to a greater or less extent, these induced currents, which, however, could always be neutralised by a suitable twist being given to the iron. An interesting question arises thereby with reference to the iron in the cores of transformers. Should the iron used in the cores of closed circuit transformers happen in some way during manufacture to gain the necessary twist, currents will be induced in this way which may prove a source of heating in the iron and thus entail loss of energy. In open circuit transformers such loss could be prevented, but will ordinarily occur should parts of the iron of the core be differently twisted from others and be uninsulated, or should there be short circuit through other parts of the apparatus. It has been doubted by some observers whether the heating in the cores of transformers can be fully accounted for by the calculated values of Foucault current and hysteresis. These Torsion Currents may in part account for the alleged discrepancy.

LIFE AND EFFICIENCY TESTS OF INCANDESCENT LAMPS.

BY CLARENCE P. FELDMANN.

It is a well-known fact that in the course of its life a glow lamp slowly decreases in candle power and efficiency, the latter being taken in its proper meaning, *i.e.*, candle-power per watt. The object I had in view in undertaking these tests was to determine the character of this decrease, especially for the so-called "low watt" incandescent lamps. For that purpose, from three to ten lamps of each make were taken, their candle power and energy consumption determined at the normal working pressure of 72 volts, and they were then run at the laboratory of the Cologne central station, measurements being repeated every 50 and in the beginning every 25 hours.

In this way I tested 106 lamps of 21 different makes. I will first refer to the results obtained with de Khotinsky lamps, as they best show the characteristic features of well made "low watt" lamps. There were in all 17 lamps, labelled 72 volts and 16 c.p., and some, in addition, $2\frac{1}{2}$ watts (per candle). The energy was measured with a Ganz wattmeter, and the candle-power with a Bunsen photometer, using the amylacetate candle as unit. With respect to their initial efficiency, using the term in its ordinary signification, they were divided into three groups :—

Group	I. :	lamps giving	20·9	candles	and taking	1·72	watts	per candle.
„	II. :	„	16·66	„	„	2·76	„	„
„	III. :	„	16·0	„	„	3·32	„	„

The curves I., II., and III., in Figs. 1 and 2 show respectively the decrease in candle power and the increase in watts per candle for Groups I., II., and III.

Table I.

Group I.

2 lamps were	broken	after	16	hrs.	1 lamp was	broken	after	246	hrs.

We see, therefore, that even lamps of low initial energy consumption may reach a high number of burning hours, but that towards the end of their life they have lost so much of their initial candle-power that it is practically impossible to run them out. Practice requires a certain minimum amount of candle power, say 50 per cent. of the initial candle-power, and this limit must be taken as a measure for the *practically useful life* of the lamps. The life, defined in this way, was :—

About 110 hours for the lamps of group I.
„ 325 „ „ „ „ II.
„ 1,050 „ „ „ „ III.

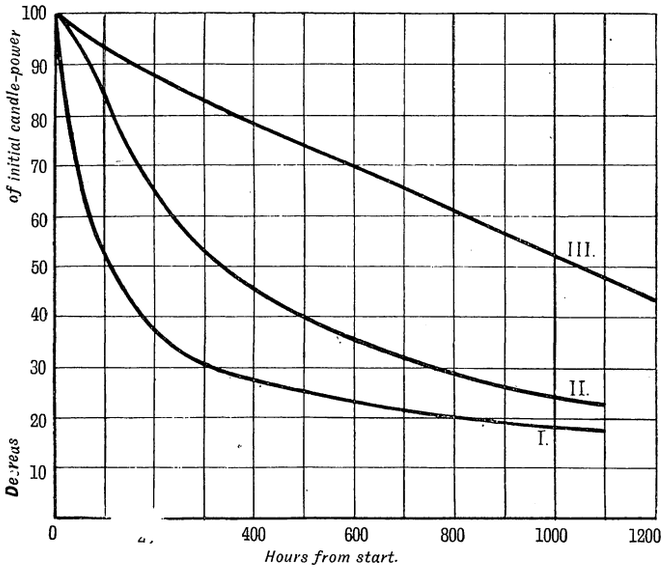

FIG. 1.—De Khotinsky Lamps.

But the lamps of Group III. are better than the other ones in other respects also. The curves of Fig. 2 show that after 130 and 170 hours respectively they reach equal efficiency with those of Group I. and II. respectively, and that for a higher number of hours they work much more economically than the latter.

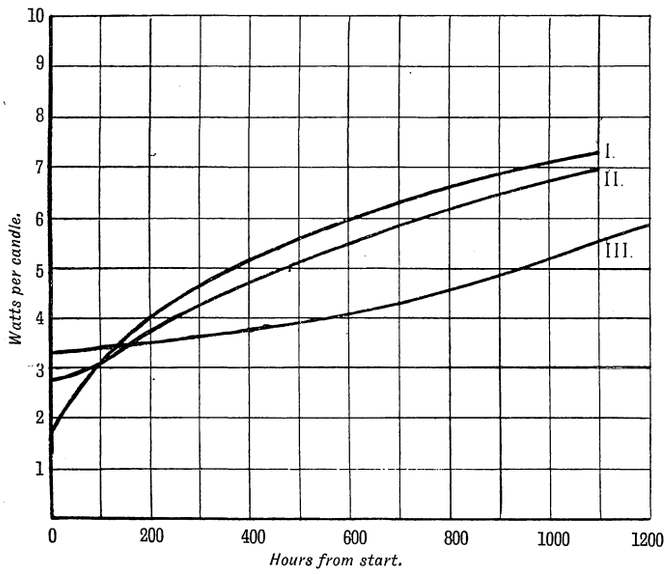

FIG. 2.—De Khotinsky Lamps.

These properties are common to all well-made lamps, not only to those of de Khotinsky. But I shall not give all the curves obtained, and I only mention (Table II.) those of the Venloo lamps, manufactured by Pope, because they show some characteristic features.

Table II. and Fig. 3 both show that the "low watt" lamps of this manufacture are better than the de Khotinsky lamps with respect to constancy of candle-power, but worse with respect to the durability of the filaments. This is especially shown by the lamps of Group E, of which

3 lamps were broken after			23	hrs.	1 lamp was broken after			108 hrs.
1 lamp was	„	„	48	„	1	„	„	112 „

All burnt out. All out. All burnt out. All out.

Taking the values of all the tests which Thomas, Martin, and Hassler, and afterwards Haubtmann made, together with the results of my own measurements, I have calculated Table III., which contains mean values for more than 500 lamps, taken from 28 different factories, and representing 49 different types.

The values given in Table III. are plotted down in Figs. 5 and 6. It may seem strange that the lamp with the highest initial consumption per candle-power is, with respect to constancy of light, worse than that taking 4 watts per candle; but this irregularity may be due to the fact that these 4·5 watt lamps, which were all of American manufacture, are some-

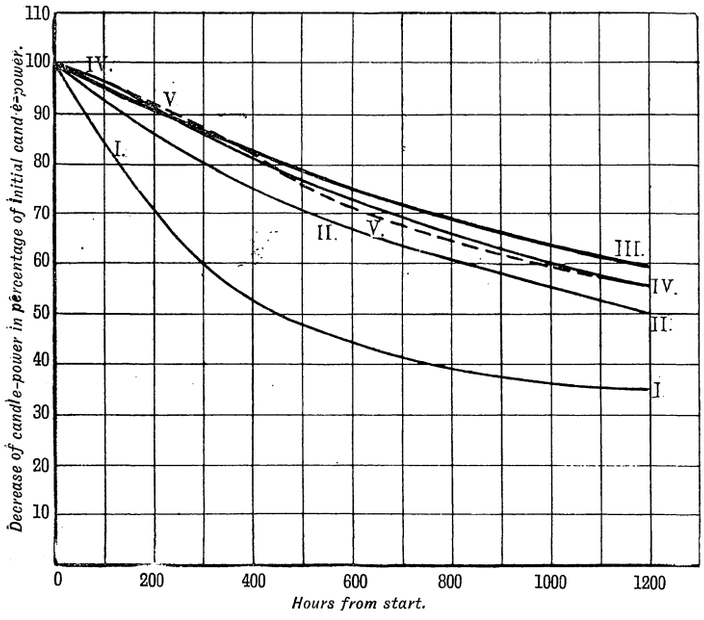

FIG. 5.—Modern Glow Lamps.

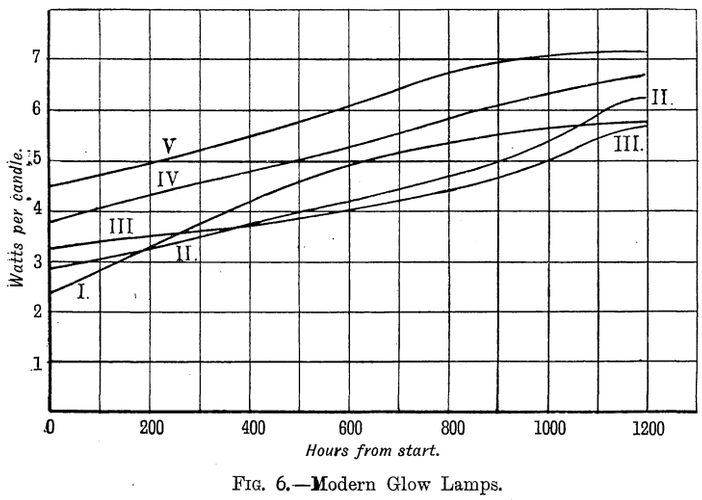

FIG. 6.—Modern Glow Lamps.

what worse than good modern lamps ought to be. What I want to emphasise, however, is that these Figs. 5 and 6 evidently show the 3·5 watt lamps (curve III.) to be the best among the modern ones, a fact which has been felt instinctively by many, but which had not, to my knowledge, yet been ascertained by exact measurements. Indirectly, these measurements, which were made with an alternating current of 50 ∽ per second, corroborate the results of Profs. Ayrton and Perry's tests, which showed that there existed no difference in the efficiency of incandescent lamps fed with continuous and alternating current.

THE PROBLEMS OF COMMERCIAL ELECTROLYSIS.

The following is an abstract of the adjourned discussion of Mr. Swinburne's Paper on "The Problems of Commercial Electrolysis," which took place on Thursday last, Nov. 17th, at the Institution of Electrical Engineers. Speakers whose remarks are prefixed by an asterisk have returned the same revised. Owing to the large number of blanks in the report which we received from the Institution of Electrical Engineers, where chemical or other technical expressions have been omitted, we have had unusual difficulty in filling in these omissions in the abstract.

Mr. G. L. ADDENBROOKE agreed with Mr. Swinburne that the methods of reduction of aluminium were simply due to the heat of the arc, and not to any chemical action. The price of aluminium six months ago was brought down to 1s. 9d. for large quantities ; it has now gone up again to 3s., and his impression was that it would continue to rise, but probably within the next 25 years aluminium would not be very much more expensive than copper, and as it was a very good conductor, since for equal weight it had double the conductivity of copper, it was not improbable it might play a very important part in the electrical industry.

Mr. LLOYD said that plating was a comparatively old industry, and that on that account Mr. Swinburne might have wasted time if he had introduced it in his Paper. Nevertheless, he thought that electro-plating with alloys was a distinct advance. He placed on the table a number of samples of alloys, and called attention to some samples of silver alloyed with cadmium, the amount of cadmium being comparatively small. He thought that palladium plating would probably come into considerable use in future, when the non-oxidisability of this metal, and the high temperature that materials coated with it would stand, became known.

*Mr. E. J. BEVAN said, with regard to Mr. Falconer's remarks, that there was nothing remarkable in the formation of chlorates ; indeed, the manufacture of potassium chlorate was one of the processes referred to by Mr. Swinburne. It depended entirely on the conditions. If they suited the conditions to make magnesium chlorate they could make it in abundance, and if they took care that these conditions did not obtain they got very little chlorate. It was interesting to note that within the last week or so Dr. Hopkinson had published a Paper, in which he stated that the cost of a kilowatt should not exceed 0·33d, which was not very far from Mr. Swinburne's figure. Mr. Swinburne assumed that a current density of 3 volts was all that was necessary. He only wished it were so ; it would reduce the cost of power very considerably. As a matter of fact, they could electrolyse sodium or any other chloride with about 2½ or 3 volts, but it would be necessary to have an exceedingly large plant to work at that voltage. In practice he had found that from 4 to 4½ volts was economical. With regard to evaporation, Mr. Swinburne said that the evaporation of the caustic liquor could be effected at such a price as would not raise the cost of the caustic more than a

Hosted by Google

shilling or two per ton. He did not see how it was possible. For every ton of caustic produced they had to manipulate and get out in solid form several tons of salt, which, of course, was a very considerable matter in the operation of evaporation. This could be got over by precipitating the alkali as bicarbonate, allowing the precipitate to settle, pouring off some of the salt solution, and re-electrolysing that. In the Le Sueur system of electrolysing caustic the anodes were ordinary gas carbon, and an arrangement was made by which these anodes as they gradually wear away could be brought down close to the cathode, the diaphragm being between. As to the commercial uses of the soda produced, Mr. Swinburne said that the presence of salts would not interfere with the action of the alkalies; he ventured to think he was somewhat in error. He had made a number of determinations some years ago with the view of showing that the purest form of caustic was the most economical form, and he found the addition of, say, 10 per cent. of salt to caustic, which was not apparently a very large amount, seriously impaired the efficiency. The results were recorded in the *Journal of the Society of Chemical Industry*. He was of opinion that the electrolytic reduction of soda would pay very handsomely.

* Mr. A. P. TROTTER, alluding to electric tanning, thought that it had been decided by Dr. Rideal that there was practically no electrolysis in that process. The suggestion of Prof. Thompson as to the effect of the electric current on osmosis in some way not yet properly understood might have extremely important effects upon industries in which electric treatment has not yet been even attempted. In the Paper by Dr. Rideal and himself, which they had communicated to the Society of Chemical Industry, nothing in the nature of a theory was put forward, but they examined various theories on electrolysis from the time of Grotius up to the present date to find one which would fit with their observations, and perhaps the most plausible was that of Clausius, who suggested that the molecules are always changing partners, and dissociation was always present to some extent, and the effect of electromotive force was to give direction to the movements already going on. In that way there is no real expenditure of work necessary, it was merely directive, and molecules were encouraged to go in one particular direction. Mr. Swinburne alluded to dyeing, or rather to the electrolytic production of dyes. The process of dyeing seemed not at all unlike that of tanning, and he threw out the suggestion that this sometimes difficult process might perhaps be facilitated by electrical treatment. Mr. Swinburne alluded in his Paper to the fact that a process ought to be remarkably good on paper before they could expect anything at all from it in practice. He would say it should be not only remarkably good on paper, but also remarkably good in the laboratory before it was fit to put in practice. He had been connected some years ago with a process which was first electrolytic and after merely chemical—the decortication of rhea fibre. The first process consisted of the electrolysis of a rather disgusting mixture of organic substances. The rhea fibre subjected to this treatment in the laboratory in small bundles was remarkably encouraging. Stuff like dried bean stalks produced hanks of a fibre very like white floss silk, but afterwards putting it on a large scale, as soon as they tried a hundredweight or more at a time it came out a tangled mass. The machinery was clogged and nothing could be done with it.

Mr. GABRIEL ANDREOLI said that he wished to take up a point in Mr. Swinburne's Paper which has already been discussed both last week and this evening. It was the point in which he says that the only difficulty in the production of alkaline is in the anodes He says that platinum is too expensive, that carbon is destroyed, and that peroxide of lead is attacked by the hydrochloric acid which is formed in the electrolysing chloride. Mr. Fitzgerald told us what peroxide of lead will do in the form of lithanode. If ordinary peroxide of lead would serve for anodes, they need not go any further. In Prof. Bartoli's researches on the action of carbon in a solution evolving oxygen, the carbon was destroyed, disintegrated, and malitic acid is formed; but it was not generally known that if they used denser solutions less oxygen was given off, and the carbon was not nearly so much attacked. If they went on reducing the solution they got chlorine only and very little oxygen, and the carbon was hardly attacked at all. The idea of replacing the ordinary bleaching process by using electrolytic bleach presented so many difficulties that it had been practically given up. There was such a large bulk of liquor to use that they lost a large amount of salt, and to avoid this loss they had to use weaker solutions which gave off oxygen, and if they used carbon anodes the carbon was destroyed. If they used weaker solutions, they decomposed the water, and had a loss of current, because they used their current up by decomposing this water, and that diminished their yield. He was interested in the question of ozone. Ozone could be applied in very many instances, more particularly to bleaching molasses and sugar. It was a very powerful disinfectant; it kills bacteria, and was used in hospitals.

Mr. COOPER said that in nearly every instance which Mr. Andreoli had mentioned they had found the difficulties which he stated, but they had got over those difficulties some years ago, and he was prepared to prove that at the present moment on the Continent they were replacing in mills bleaching paper, pulp, cotton, and yarn, the equivalent of 3,000 tons of bleaching powder per annum.

* Mr. BLOUNT referred to the production of copper from the ore or from the matte direct. The refining of copper was quite a different thing from the winning of it, either from the matte or from the ore itself. Although the refining of copper from crude copper cast into suitable anodes was very hopeful, still greater advances would be made when the ore itself, or, if that be impracticable, the matte, was treated directly with commercial success. The whole difficulty in the Höpfner process seemed to be the one indicated by Mr. Swinburne in the electrolytic production of alkali, that was the question of an anode. The anode was always to trouble us—an anode might be excellent in every way, but either it would not stand, or if it would stand, it would not conduct.

* Mr. SWAN (in a communication read by Mr. Mordey) asked for further information regarding the cost of a kilowatt at a farthing an hour. He alluded to a detailed description which appeared in the *Scientific American* of plating large pillars with aluminium. Dr. Hopfner's process was: Instead of electrolysing sulphate of copper-solution, Dr. Hopfner employs a solution of cuprous chloride ($Cu_2 Cl_2$) as the electrolyte, and after the partial deposition of the copper and raising of the cuprous chloride to cupric chloride ($Cu Cl_2$), he reproduces the cuprous chloride by treating the cupric chloride with ore obtaining sulphur at the same time. In connection with the question of the electrolytic extraction of zinc, he might remark that there was great room for improvement on the ordinary process of zinc smelting. There was a loss of 20 to 30 per cent. of the metal. The inducement to effort to improve this process by electrical or any means was very strong. Among the electrolytic processes, one of the most recent and perhaps one of the most hopeful, Burghardt's was not named. Burghardt proposed to deposit zinc from a solution of zincate of soda.

* Mr. MORDEY, referring to the troubles experienced with carbon electrodes, said that in making class experiments on the electrolysis of water, using acidulated water and carbon electrodes, he found the mixed gases did not explode. He found this was due to the evolution of CO_2. In the Paper written in June, 1833, Faraday pointed out that CO_2 and CO are given off abundantly when water is electrolysed with carbon electrolysed—a fact that did not appear to be generally known

Mr. RICHARDSON described a process of bleaching which was being used in connection with a paper mill. They found that carbon disintegrated at a very rapid rate under certain circumstances. But its disintegration did not by any means preclude its application to the particular purpose of decomposing salts. It had been remarked that the carbon came off in a very fine, almost an infinitesimal division. Nothing of the kind: sometimes it came off in lengths of one-eighth of an inch, sometimes one-sixteenth of an inch, and sometimes almost half an inch, as though there were something relative to its conductivity.

* The PRESIDENT said that the question whether Mr. Mordey's experiment depended on electro-chemical or an electrolytic action seemed to be one of very great importance. If it was only a chemical action, it was simply heating the cell; then it was like any burning and was not of importance. If it was really an electrolytic action, then he had decomposed water and formed carbon di-oxide. Of course the heat of combustion of hydrogen was greater than the combustion of an equivalent amount of carbon, and therefore an amount of energy was required to produce that process. If they took a substance which when oxidised had a less heat of combustion than carbon, then if what Mr. Mordey had found was really an electrolytic process, it would be possible to obtain electrical energy by the combustion of carbon, an easy method for doing which is the one thing which so many of them had been seeking for a long time. It would mean, therefore, that they would then have an electric cell in which the positive substance would be carbon. He could hardly hope for such an easy solution of the process. The President then described the application of an electric current to overcome the "sickening" of mercury in the extraction of gold. Hydrogen was produced at the surfaces of the mercury which cleaned the mercury and so exposed a fresh surface to the gold. He had made experiments with similar tubes of mercury, and put similar particles of gold on the top, and then sent a current for a certain number of hours through one tube, and no current at all through the other. In the morning, or the day after, he analysed the layers of mercury in each of the two vertical tubes, and in the case of the one without current the mercury at the bottom was pure, and in the one with current the mercury at the bottom contained a good deal of gold, showing that the mere passage of current conveyed gold down to the bottom of the mercury. He described experiments, made with Prof. Perry, to see if it was not possible to produce a voltaic cell—a primary cell—by using this idea of transference of one material through another, so as to produce these effects without any electrolysis at all. That particular cell was a sell in two senses of the word. The observed effects were probably due to difference of temperature. Still, he thought it might be possible to really get E.M.F. without electrolysis, because they certainly seemed to be able to do the converse by means of the current—to pass one substance through another without any electrolysis in the ordinary sense of the word.

Mr. ALEX. SINCLAIR had sent a communication, which was read. He found himself at variance with Mr. Swinburne as to the cost per kilowatt-hour, which he placed so low as 0·25d. Mr. Swinburne assumed generally that one kilowatt was equal to a certain amount of electrolytic work, so it was, but, unfortunately, that kilowatt contained E.M.F., a constantly varying quantity, according to the materials used as electrolyte or electrodes. The electrolytic treatment of zinc suffered very much from insoluble anodes and high power. What was required there was a good anode, homogeneous deposit, and a means to prevent a decomposition of water and consequent loss of power. Under the most favourable circumstances 400 kilowatt-hours are required to deposit one ton of copper, which, taken at ½d. per kilowatt, would be 16s. 8d. Again, the fact of having to roll the copper to a quarter or three-eighths of an inch thick and then cast to shape cost from 15s. to £1 per ton, these items in themselves come to more than the price given; probably some three to four times that figure would be the better value, and even on to that must be added the after treatment of the copper and bullion recovered. Some of the problems required to be overcome were—The production of a really good insoluble anode; the discovery of a good diaphragm, which will stand the test of time; the prevention of the formation of a back E.M.F. when insoluble anodes are used; the prevention of decomposition of water; the production of pure deposits from impure materials; the combinations and effects of such impurities on the resistance of the electrodes; and the means to reduce the resistance of electrolyte so as to minimise the quantity of power required.

* Mr. SWINBURNE, in reply to the discussion, said that Mr. Falkenstein had pointed out in the beginning of his remarks that tan liquor was colloidal, and then he went on to say that the tanning was due to electric

Hosted by Google

osmosis. These statements did not seem to agree very well. A colloid could not work by osmosis. He read to the meeting the following estimate of cost of running a plant continuously day and night :—

Output 1,000,000 watts. Engine and dynamo combined efficiency 85%.

Coal, at 2lb. per I.H.P. per hour, at 10s.	£5,850
Oil, waste and sundries	700
Three shifts of engineers at 35s., and two shifts of three stokers at 24s.	657
Interest at 3% and depreciation at 5% on £20,000	1,600
	£8,807

Coming to 0·241d. per kilowatt hour.

He was afraid he did not put the matter clearly enough about the anodes, and thought there had been considerable confusion. An anode in an alkaline solution was one thing and in an acid solution quite another. He thought that Mr. Fitzgerald's experiments of producing hypochlorite by means of lithanode might overcome a difficulty in bleaching liquid, but had no bearing as far as he could see on the manufacture of caustic soda. Mr. Falconer had mentioned that the platinum was attacked when used as a connection to his lithanode. He thought the mere fact of platinum being attacked showed that the anode was trying to give off chlorine and not hypochlorite. He was glad to get some information from Mr. Bevan about the E.M.F. he considered necessary in working chloride solutions. He said 3 volts. Of course, if they used a weak solution their plant account became large ; that is to say, they had very little output for very large vats. Those who had calculated it were probably surprised to find the size of vats necessary to give a ton of caustic per day. Again, if they ran a high current density with high volts, they lost power by losing the E.M.F. of course, and that would tend to disintegrate the anode, so that the whole question became one of compromise. As to the theory of tanning, Mr. Trotter ought to have found fault with the theory he advanced before saying there was not a theory. He would only refer to the President's remark as to the possible use of carbon. If the burning of the carbon in the CO_2 does help the E.M.F., of course they could not make ordinary cells with carbon plates, carbon to zinc, and so on, but they always used carbon on the depolariser side, and not on the other side.

DINNER OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

The fourth annual dinner of the Institution of Electrical Engineers took place at the Criterion Restaurant, Piccadilly, on Friday evening last, Prof. W. E. Ayrton, the President of the Institution, presiding. Amongst those present were the Right Hon. A. J. Mundella, M.P., President of the Board of Trade ; Sir Courtenay Boyle, K.C.B. ; Mr. Latimer Clark, Mr. W. H. Preece, Major-General C. E. Webber, C.B. ; Prof. W. Crookes, Mr. C. E. Spagnoletti and Prof. D. E. Hughes, Past Presidents ; Dr. William Anderson, F.R.S., President of the Institution of Mechanical Engineers ; Sir James Sivewright, K.C.M.G., Commissioner of Public Works, Cape Colony ; Sir Thomas Blomefield, Bart. ; Prof. G. F. Fitzgerald, F.R.S., President of the Physical Society ; Dr. W. J. Russell, Past President of the Chemical Society ; Sir Robert Rawlinson, K.C.B., Vice-President of the Institution of Civil Engineers ; Prof. James Dewar, of the Royal Institution ; Prof. W. C. Unwin, Dean of the City and Guilds of London Central Institution ; Mr. W. H. M. Christie, Astronomer Royal ; Mr. J. C. Lamb, C.M.G. ; Sir H. Trueman Wood, Secretary of the Society of Arts ; Sir Henry Mance, C.I.E. ; Sir David Salomons, Bart. ; Mr. A. Siemens and Mr. R. E. Crompton, Vice-Presidents of the Institution ; and the following members of the Council : Prof. S. P. Thompson, Prof. J. A. Fleming, Sir Albert J. L. Cappel, K.C.I.E. ; Colonel R. R. Jackson, Mr. Mordey, Mr. Swinburne, and Prof. Perry, and Mr. Webb, secretary.

The toast of "The Queen" having been drunk, the toast of "The Learned Societies," coupled with the name of Prof. Fitzgerald, was proposed by the CHAIRMAN, who said that some difficulty had been felt in the wording of the toast list. It was thought that to have two toasts, "The Learned Societies," "The Engineering Societies," might suggest that the latter were not learned ; but the inference would be entirely wrong. There was no "and" in the matter.

Prof. FITZGERALD, in response, thought that the learned societies were never in a more flourishing condition than they were at present. He was quite sure they felt that they owed much to such electrical engineers as Gilbert, Galvani, Volta, Oersted, Ampère, Gauss, Weber, Faraday, and Maxwell. The co-operation of theory and practice had already produced great results, and he ascribed nearly all the material advances of the nineteenth century to that co-operation. There was plenty of room for further development, however. It had been calculated that the amount of energy received from the sun would be sufficient to supply the energy required by five people living upon every square yard of the earth's surface ; and though such a large population would find it very close quarters he was afraid, they thought that with these enormous stores of energy at their disposal there was a great future for its proper distribution and utilisation. The small advances that had been made hitherto had been effected by the co-operation of a comparatively small section of the community, and they might look to far greater advances in the future when the whole community conspired together to advance the material prospects of mankind to their utmost by the combination of theory with practice.

Mr. LATIMER CLARK (past President) proposed "The Engineering Societies." He thought their importance was liable to be very much under-rated and overlooked. He felt that the engineering societies had a grievance against the politicians. He ascribed the credit for the extreme prosperity of the country to the efforts of the engineers, but politicians seemed to think it was due to political measures. The facilities for communication and transport which had been provided by engineers had made England the richest nation in the world.

Dr. WILLIAM ANDERSON, in responding, referred to the definition of engineering as the art of directing the great sources of power in nature to the use and convenience of man, and said this capacious definition would include every work and every art. In the Government factories of which he was the head, they called upon every art to assist them in preparing munitions of war, and the members of their Institution played a very important part in the preparation of those delicate electrical fuses constituting the apparatus for exploding submarine mines. They were now able, in consequence of the extraordinarily small intervals of time which could now be measured by electrical means, to determine with considerable success the relations between velocity and space in regard to the bore of guns, from which it would be possible to derive velocity curves, and from them the pressure curves, telling them with exactness what took place in the bore of cannon, and this could only be effected by electricians, physicists, and chemists combining together. Then the mechanical engineer came in, and taking the calculations of the mathematician to work upon, evolved ponderous cannon with an exactness that might be fairly expected from mathematical instruments alone.

The CHAIRMAN then proposed "Our Guests," with which he joined the name of Mr. Mundella, President of the Board of Trade, who exercised a sort of parental supervision over the actions of electric lighting engineers. Sometimes, he admitted, there was a little uneasiness and irritability between them, and this year sparks had been seen flying between a town in Essex and Whitehall-place, sparks which the Meteorological Society had put down as unusual electrical disturbances. As those who had taken exception to some of the Board of Trade rules were exactly those with whom electric cooking had found most favour, it might be imagined that the objections were made in order to assert the right of every freeborn Briton to fry himself electrically on the high pressure overhead wires, but he was told that was not really the ground of their contention, but that it was because the "undertakers" had been required to bury their wires. It had been contended that some of the wires were out of town, and must therefore be regarded as non-resident members of the machinery for the distribution of electricity, but to that the Board of Trade replied that only those who were thin-skinned could experience pain at their rules. As a matter of fact, the point could only be felt by those, the thickness of whose electrical epidermis, expressed in inches and fractions of an inch, was less than the number obtained by dividing the pressure to which the Board of Trade had been subjected in volts by ten times the number of the members of their Institution. The question really was as to the relative durability of insulating material and the lasting power of Board of Trade regulations. Whatever might be their feeling about the regulations, however, there was no question as to their regard for the head of the Board of Trade.

Mr. MUNDELLA, in response, said that whatever the grievances of engineers might be against politicians, at least he could say that his withers were unwrung. In the short time during which he was at the Board of Trade in 1886 he had learnt that the Act of 1882 was altogether too restrictive, that it impeded enterprise, and that it had done much to delay the development of electrical engineering in this country. At that time, however, they were not so well prepared for an extension in electrical enterprise, and if it had delayed for a time the development of electric lighting, yet during that time much had been done to perfect their methods and improve their practical experience. As to the grievance referred to by Mr. Clark, he thought if politicians and engineers divided the credit for the prosperity of the country there would be a little more fairness in the appropriation to each of the merit which was their due. They all knew what the country owed to engineering. In a little musuem at South Kensington might be seen one of the most interesting collections in the world, including such curiosities as Watt's steam engine, and Stephenson's Rocket, but it must not be forgotten that it was Sir Robert Peel and the free traders who gave free play to the energies of these men, and if we had now the greatest mercantile marine, and had become the carriers of the world, it was partly owing to that free play. He felt it very difficult to speak on that branch of engineering of which they were the great masters. They were a comparatively young Institution, and for many years, probably centuries, they would continue to grow in importance and power. The Board of Trade owed much to the members of their Institution who had co-operated with them in fixing electrical standards. They had made a report which for ingenuity and ability was one of the most remarkable which the Department had ever had to deal with. This report would have to be embodied in an Order in Council, and submitted to Her Majesty for approval, and if approved would form the standard of electrical measurement for all future time. They owed a great deal to Prof. Helmholtz and the German Government for their co-operation with the English committee, and practically their standards would be the same. He was afraid, however, that he should find a difficulty in lucidly explaining, if called upon in the House of Commons or the Privy Council, what was so

Hosted by Google

learnedly set forth in these recommendations. For example, if he were asked about alternating amperes, here was his answer, in one sentence with no punctuation :—"An alternating current of one ampere shall mean a current such that the square root of the time average and the square root of its strength at each instant in amperes is unity." Did anybody doubt it? Any man who called that in question could know nothing at all about the subject. However, they had helped the Board to fix an admirable standard for electric measurement in this country, and which would, he hoped, result in an international agreement upon a common standard. To secure the universality of electric lighting they had to show that they could give the shareholders a reasonable dividend ; when they had done that, there would be no lack of enterprise and no lack of money to carry it on. A marvellous change had been wrought in commerce by the introduction of the electric cable, which to-day equalised prices throughout the world, and they were making great advances in other directions. There was a Royal Commission, on which some of the members of that Institution were sitting to consider the utilisation of electricity for the saving of life at sea by connecting lighthouses and lightships with the electric system on our coasts, and he might congratulate them on the fact that one distinguished member of their body had been that day appointed to serve on that Commission—he referred to Mr. Preece. They might hear occasional grumbles about Board of Trade regulations, but these were only the expression of their desire for safety, and it was a creditable thing that the loss of life in this country in connection with electric lighting since its introduction was exceeded every year in some American towns. They had adopted, he believed, a sound system of regulations, the result of which would be a career of prosperity and success for their enterprise, which neither he nor his colleagues on the Board of Trade had any desire to harass. They would be glad if in the application of electricity, as in every other science, England held her own against the rest of the world.

Sir JAMES SIVEWRIGHT, K.C.M.G., in proposing "The Institution of Electrical Engineers," said they all wished well to the Institution. In South Africa telegraphic engineering, with which he had been connected all his life, was playing a very important part to-day. When Mr. Rhodes returned to South Africa a few years ago with the Royal Charter which had been granted to him by Her Majesty's Government of that day, and when they were considering how, according to the terms of the charter, they might best develop the country, Mr. Rhodes had asked what he thought they should start with. He replied, push a telegraph line right into the heart of the country. The estimated cost was £100,000 ; they had undertaken that work, and were now stretching a line, which would compare favourably with lines in any other part of the world, 1,800 miles into the heart of Africa. They had been studying the navigation of the Zambesi and Shire waters, and had now finally decided to extend that line 300 miles further into the interior, so as to place Mr. H. H. Johnston and others in telegraphic communication with the civilised world. Their efforts in these distant corners of the empire were the fruit of the improvements effected in the means of communication by electrical engineers in this country. He would like to put in a word for the telegraphic engineers—the practical men who were doing this work in South Africa, and it should be remembered that the Institution of Electrical Engineers had its first beginnings in the old Society of the telegraphic engineers. They were very proud of the body to which they belonged, and that body need not be ashamed of the men who were upholding the name of the Institution. Mr. Mundella had said that the electrical engineers, as a body, would increase in importance—it might be for centuries ; he would go further, and say that they would so increase as long as England continued to be England. He was sure there would never be a lack of men connected with the Institution competent to uphold the reputation it had already acquired.

The PRESIDENT briefly responded, and the proceedings then terminated.

GAS-ENGINE EXHAUST.*

BY P. SIMON.

Engines in general and gas engines in particular exhaust in a rather noisy way, and the result is a good deal of bother in the way of complaints from neighbours, legal actions, &c. I undertook a series of investigations into this matter, which I may, perhaps, make public some day. However that may be, it may prove of interest if I now point out a method which I have tried and adopted for the purpose of putting a stop to, or at any rate mitigating, as far as possible, the noise produced.

First of all, I should point out that the noise is of two kinds. There is firstly a blow at every escape, and secondly, a note given out by the escape of the gases under pressure ; a note which is always given out, be the exhaust spasmodic or regular. As a matter of fact the shocks are mitigated by regulating the flow of the gases by means of exhaust chambers, which play the same part as the air chambers of double-acting pumps. Unfortunately, this remedy is limited by the danger of filling large receivers with gases which may have escaped combustion in the cylinder and thus give rise to dangerous explosions. Moreover, this method of regulation involves a back pressure, and it cannot, therefore, be carried far without diminishing the useful effort of the engine. This remedy has, therefore, a limited range of action.

What is wanted is a gradual and insensible diminution of the average velocity of the exhaust gases. The variations of pressure and consequently of volume would thus be rendered very small, and the violence of the blows would be diminished, whilst the exhaust gases having a lower velocity would no longer give a noisy note. A system of very acute angled conical tubes has been tried by myself and others. The insensible increase of cross-section produces a gradual diminution of velocity. Unfortunately, when the diameter approaches a certain value, the velocity of the gases is no longer the same over any given section, owing to the friction of the walls, and the result is a series of whirls which make the tubes quiver, thus producing an effect the reverse of what was intended.

I have substituted for these cones a single straight pipe, split for a distance of about two metres. The opening, very narrow at the bottom, widens out until it attains a width equal to the diameter of the tube. The effect produced is remarkable when it has been possible to give an appropriate width to the cut by trial and error. It is not an easy matter to split a tube in this way by means of ordinary tools, and alterations are a lengthy job. I have considerably simplified matters by giving the tube a long longitudinal saw cut ; the two halves are then drawn apart and kept apart by wedges and rings. The puff of exhaust gas spreads out in a fan, and the passage from the tube to the open air takes place very gradually.

Such is the method, at the same time simple and cheap, which I have employed to my own great satisfaction, and especially to that of my neighbours whose rest was disturbed. Applied to a non-spasmodic escape of steam, this simple split tube has reduced a strident noise to very modest proportions.

* From *L'Électricien*.

BOOKS, &c., RECEIVED.

"Campo Elettrico Rotante e Rotazioni dovute all' isterisi Elettrostatico." By R. Arnó. (Rome : Academia dei Lincei.)

"Proceedings of the Royal Society." Vol. LII., No. 316. (London : Harrison and Sons.)

"Electric Traction on Railways and Tramways." By A. Reckenzaun. Illustrated. (London : Biggs and Co.) 400 pp. Crown 8vo.

"Direct Electric Tramway Traction." (London : F. G. Wynne.)

"First Report of the Bureau of Mines, 1891." Printed by order of the Legislative Assembly of Ontario.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, November 25th.

PHYSICAL SOCIETY.

5 p.m. Paper to be read :—"Experiments in Electric and Magnetic Fields, Constant and Varying," by E. C. Rimington and E. Wythe Smith.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read :—"The Telephone," by Howard Little.

MONDAY, November 28th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture. I., 2, "The Generation of Light from Coal Gas," by Prof. Vivian B. Lewes.

TUESDAY, November 29th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read with a view to discussion :—"The Manufacture of Small Arms," by John Rigby, M.A.

WEDNESDAY, November 30th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read :—"The Copper Resources of the United States," by James Douglas.

OLD STUDENTS' ASSOCIATION.

8 p.m. Meeting at Finsbury Technical College. Presidental Address, "Human Dynamics," by Ll. B. Atkinson.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Conversazione at St. James's Hall Restaurant.

THURSDAY, December 1st.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be discussed :—"Experimental Researches on Alternate Current Transformers," by Dr. J. A. Fleming, F.R.S.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting. Paper to be read :—"On the Formation of Orcinol and other Condensation Products from Dehydracetic Acid," by J. Norman Collie.

FRIDAY, December 2nd.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Ordinary Meeting. Paper to be read :—"Water-tube Steam Boilers," by Harry Fraser.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

NOW READY.

Volume XXIX. of "THE ELECTRICIAN," price 12/6; post free, 13/6 abroad carriage extra.

Cases for binding Volume XXIX., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

CYRUS W. FIELD.

With "THE ELECTRICIAN" for Oct. 28 was issued a Fine Steel-Plate Portrait of the late CYRUS W. FIELD, Pioneer of Ocean Telegraphy. Copies can be supplied, price 1/0, on roller 1/2, post free.

SCIENCE IN SCHOOLS.

In these days of hurry, competition, and democracy there is little time for culture and little heed for refinement. Men who from their youth are driven into commerce or trade, occasionally snatching an hour or two for exercise of the body and to rest the brain, have no leisure worthy of the name, and it is not surprising that, with the consequent neglect of literature, marked changes are to be found in education. A generation or two ago, a successful cheesemonger would give his son a literary education "to make a gentleman of him," with the idea of giving the lad something which the father did not possess. But now, in the race for that which is called social success, money plays so important a part that it is found Latin and Greek do not work the spell, and these being, therefore, "useless," boys have to be taught something "useful." To supply the want, a modern language or two, a trifle more mathematics, and history in its most dreary form are taught on the "modern" side, together with a smattering of science, and though generally disfavoured by the clerical element which still pervades the better class of English schools, science has made its way. Little or no pretence is made as to its educational value, and it is indeed idle to discuss an ideal system of education when not one parent in five hundred would venture from the conventional path. Whether the teaching of science to boys under eighteen is desirable or no does not concern us at present. It is taught, and will be taught, and it remains for those who are interested in it to justify the practice as well as they can.

The progress made in schools in the teaching of science has been mainly determined by the growing importance of the subject from an industrial point of view. Its advancement

Hosted by Google

has been mostly retarded by the system of oral instruction to which school teachers are addicted, and the restriction of it to subjects which have been most important in their own student days. But schools, although naturally very conservative, are keenly sensitive to competition. The newer schools, like the newer universities, have found that to lay stress on the development of a modern side will pay them best, and sooner or later most of the older ones will be compelled to follow their example. The distinct propensity of the time is to specialise, even at school. For many reasons this may be regretted, yet the division of the upper forms into classical, commercial, and scientific classes has been rendered necessary by the increase in the number of subjects of recognised importance, and the excellent excuse is put forward that a boy can spend his time on studies which bring out his brighter faculties, rather than waste a large part of it on comparatively vain efforts in other directions. Were it not for this bias towards specialism it would be impossible, during the brief school hours, to devote more time to science than is needed for the merest smattering of it. No doubt to over-specialise is bad, yet it cannot be worse than the endeavour to acquire a mass of superficial knowledge at a rate which does not admit of a proper expenditure of thought. The hitherto abstruse and mysterious aspect of science has been one of the great obstacles to its introduction into schools. It appeared to stand apart from the feelings and ideas of everyday life. To fit up a physical laboratory with apparatus, purchased entirely from instrument makers, requires more money thay any but an exceptionally endowed school can afford; and the ordinary master, whose training at school and university has been chiefly oral, does not possess the manual skill needed for supplementing a few good instruments with a number of cheap home-made pieces of apparatus. This difficulty is gradually disappearing with the introduction of manual instruction into schools, and with the improvements in the physical laboratories possessed by various colleges. Moreover, the abstract appearance of science is being quite changed owing to the increase in the number of its commercial applications. Of all the sciences, electricity and magnetism are the two which in the popular estimation are most enveloped in mystery, yet so many illustrations of them can now be drawn from everyday experience that the elementary facts of these sciences have no longer the aspect of propositions in Euclid, but are becoming generally familiar as tangible things. With so-called technical education we are not here concerned, we have on several occasions objected to the inclusion of the teaching of a trade under the name of education, whether at Cambridge or at Kensington. In its proper place this secondary education or technical instruction is, of course, invaluable, and an abstract of a very interesting article upon this subject, by Mr. Henry Cunynghame, will be found in another column.

The rate at which the teaching of science is progressing cannot be properly realised unless it is remembered that thirty years ago there was hardly a physical laboratory in the kingdom. Teaching was confined to lectures containing a great deal of mathematics but very little experimenting, and to a course of unintelligent "test-tubing." The teaching of physics was subordinated to that of chemistry, and was in many cases placed in charge of a chemist. In modern days we can boast the possession of many fine laboratories set apart for physical science alone, and in these not the professor only with a few favoured helpers, but the ordinary student also may be now seen at work. The agitation in favour of technical education has in late years caused large sums to be expended on the erection of good laboratories, although we are even now a long way behind the Continent in the provision of space and apparatus for individual work. Schools, such as those at Manchester and Birmingham, have been erected exclusively for the teaching and applications of science; and in America, where the average undergraduate is but slightly older than the boys in the upper forms of English colleges, such schools are common enough. The science examinations at the London University are attended by candidates from all parts of the kingdom, and form a good criterion of the progress of science teaching in this country. We notice that the number of successful candidates at the Intermediate and Degree examinations in science has quadrupled during the last ten years, and that of these candidates one out of every seven was a lady. Physical science cannot indeed claim to be exclusively masculine, and several ladies' colleges could be cited where the provision for science compares very favourably with that found in similar institutions for men. The science examinations just referred to are supplemented with practical tests. The candidates in the Intermediate examination are required to show familiarity with the use of physical apparatus, and in the final examination a more searching test is applied. These practical tests have been instituted only within the last three or four years, and we understand that the average proficiency of the candidates has shown a marked improvement during that space of time. An official announcement of this University has lately been made with reference to the entrance or matriculation examination, to the effect that candidates "will find it an advantage to have obtained some elementary instruction in the practical use of apparatus." This seems to foreshadow that a practical test will eventually be applied even at matriculation. This departure can hardly fail to have influence in improving the science teaching of schools. Every candidate for a degree is obliged to pass the matriculation examination, whether ultimately pursuing science or not, a great number of schools sending up as many candidates as possible for this test, since the passing of the examination is regarded as a certificate of a good school education. These regulations are significant, because such examinations are the standard by which English high schools judge their own efficiency, and in this respect have a more important influence upon the public schools than that exercised by the older universities.

THE GENOA CONTINUOUS CURRENT TRANSMISSION.

Mention has frequently been made in these columns of the 6,000-volt continuous current transmission plant laid down by MM. Cuenod-Sautter, of Geneva, for the purpose of supplying power to the dynamos of the Société Génoise d'Électricité, and to other concerns. The following details, however, from *L'Electricien*, are of interest:—

Power is derived from the Ferrari-Galliera aqueduct at a point some 16 miles from Genoa. Three turbines each drive two separately excited Thury 1,000-volt 45-ampere dynamos; the speed of the turbines and the current of the machines being automatically kept constant. The line, which is of bare wire, is carried on oil insulators, and runs underground on entering the town. The positive lead is protected as it leaves the generating station by an Elihu Thomson electro-magnetic arc-breaking lightning guard. The return lead, on the other hand, was until recently provided merely with an ordinary saw-tooth lightning protector, with the result that the earths on the intermediate stations caused persistent arcs to earth.

At Genoa the current is fed into three Thury motors belt-coupled to a countershaft, from which four low-pressure machines are run. These dynamos supply current to a three-wire 230-volt system. As the low-pressure machines are of the ordinary constant-potential constant-speed type, the con-

Hosted by Google

stant-current motors have to be kept running at a rigorously-constant speed whatever the load, and this is effected by an automatic regulator acting on the field excitation of the motors.

The main excitation of the motors is supplied by a large number of series coils in the usual way. The additional excitation required as the motor load is increased is furnished by pairs of coils arranged on diametrically opposite pole-pieces. The + and − ends of these coils are connected to a regulating switch S, as shown in Fig. 1, the main exciting coil being taken

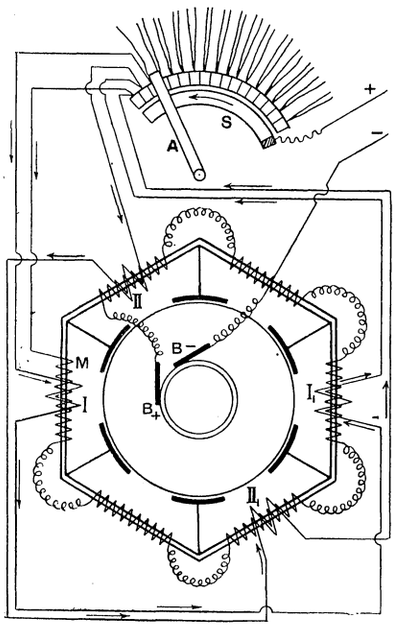

FIG. 1.

to the left-hand segment. The current from the line comes to the strip S, passes across the revolving arm A to the additional excitation coil I, thence to I_1, back to the switch, thence through the additional coils II and II_1, again back to the switch, and thence through the main coils M to the brush B+, through the armature to line by the brush B−. The revolving arm A is rotated by the motions of a centrifugal governor. A toothed disc D (Fig. 2), formed by the juxtaposition of two truncated cones, is placed on the same shaft as the governor balls. Above and below this disc are two mitre wheels, W_1 and W_2, having on their axes the pinions w_1 and w_2, gearing with a toothed wheel, which transmits its motion by an endless screw (not shown) to the revolving arm A.

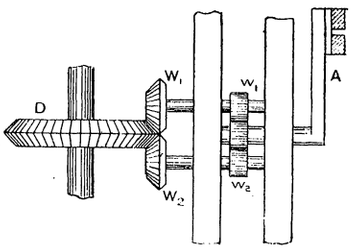

FIG. 2.

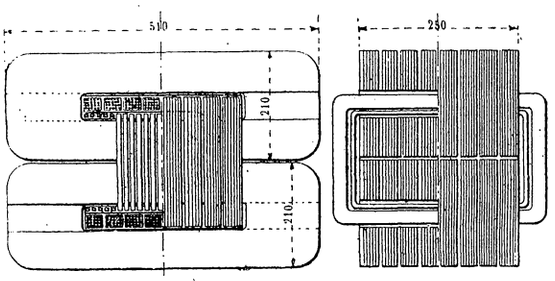
When the speed is normal the disc D is in contact neither with W_1 nor with W_2; but as soon as it increases above or falls below the normal, the disc engages with one or the other of the mitre wheels, and the arm A is suitably rotated.

By its agreement with the Société de l'Aqueduc Ferrari-Galliera, the Société Génoise d'Électricité has to pay a fixed charge of 300fr. per horse-power year demanded, so that it is obviously to the advantage of the Electric Light Company both to keep down the maximum amount it has to demand and to make the maximum use of the amount actually demanded. Secondary batteries are, therefore, made considerable use of in Genoa, and in order that the dynamos may be able to supply the mains at the same time as they are charging the cells, the battery voltage of 310 to 320 volts is kept down to the proper amount by a compensating dynamo placed in series, its field being regulated as required. The ordinary regulation of the voltage of the cells is carried out automatically by means of electro-magnetic devices for switching cells in and out.

THE PATIN TRANSFORMER.

The Patin transformer, says M. F. Guilbert in *La Lumière Electrique*, has the shape of a rectangular parallelopiped. The secondary is next the core, the primary, which consists of eight coils, being wound in rectangular tubes of insulating material. The core consists of U-shaped stampings insulated from each other with paper, and arranged side by side in two groups, as shown in the accompanying figure. The stampings are com-



Patin Transformer. End View and Lateral View.

pressed by end plates and bolts, the upper plate carrying the terminals, cut-outs, &c., &c., on a slab of marble. Owing to the manner in which the stampings are arranged there is a sort of thin chimney between the two groups. The primary fuses are long glass tubes with expansions at regular intervals, containing a fuse wire soldered to the terminal metal caps. The tubes are fitted with an ebonite handle in the middle to facilitate their being placed in position. The following data relate respectively to a 4-unit and an 8-unit Patin transformer:—

Primary.

TECHNICAL EDUCATION: "WHAT IT IS."*

BY HENRY CUNYNGHAME.

The object of general education is to train up good, wise, and useful men, sound in mind and in body. The object of technical education is to make good industrial workmen.

If we inquire what are the qualities which go to make up a good workman, whether he be the manager of a business, or an operative, we find they may be grouped under two heads—moral and technical. The former are, perhaps, the more important to success. But these do not come within the scope of our present inquiry. The technical qualities are five in number:—(1) Inventive or constructive power. (2) Artistic feeling. (3) Knowledge of the principles of science and art. (4) Knowledge how to apply

* Abstract from "Cassell's New Technical Educator."

Hosted by Google

these principles practically. (5) Hand, or manipulative skill. Of these, the first two come mostly by nature, but they can be immensely improved by training. Englishmen possess them both to a remarkable degree, for the people of Great Britian are very inventive, and have naturally considerable artistic gifts, especially in their taste for colour.

If, on the one hand, art and invention are natural gifts, on the other scientific knowledge is the reward of industry. The poet may be born, but the orator is made, and so far as knowledge is concerned, resolute perseverance generally counts for more than the most brilliant gifts. The German nation is an excellent example of this. They have not displayed of late years any very shining ability in art, poetry, literature, or mechanics; and yet by sheer work they have acquired a first-rate place in almost all branches of knowledge and industry.

The use of the knowledge of principles, as compared with the mere routine of the workshop, cannot be overrated. It is this which distinguishes the true mechanic from the mere factory hand. It is this that makes work a pleasure instead of a drudgery, and it is only by knowledge of principles that inventions can be made.

In olden days trades were chiefly in the hands of privileged bodies of men, and the right to practise them could only be obtained after a long and wearisome apprenticeship. The old apprenticeship system has, however, broken down, and there appears little probability of its restoration. The causes of this are partly the spread of trade secrets by means of printing, partly the disorganisation of our social life by means of railways, partly increased facilities for emigration, and partly the introduction of machinery, and the consequent development of the factory system. The result has been bad. In spite of our great improvements in knowledge and invention, the workman has not kept pace with the time. Boys are far too soon liberated from the healthy control of their parents or foremen, and they are far too anxious to earn immediate wages, rather than to look to more distant but higher remuneration.

If this movement continues, the effect will be to drive from England all the trades requiring high knowledge or delicate skill, and to leave us in possession only of those which are conducted by a highly educated body of foremen or engineers, directing labour of a dull and unintelligent order. This would be deeply regrettable, and would also infallibly end in the lowering of wages. It is, therefore, highly necessary, not only for the general prospects of manufacture in Great Britain, but also for the prospects of our workmen, that some effort should be made to replace or supplement the apprenticeship system by means of technical education.

Learning of all kinds may be pursued from one of two motives, either from the pleasure it gives and its ennobling effect, or else as a means of gaining money. In the very materialistic age in which we live, when each successive year shows a decreasing desire for ideals, and an increasing desire of all classes for comforts and luxuries, when philanthropy, legislation, and politics are directed principally to increase our material welfare, when, in fact, the age is almost wholly dominated by epicurean philosophy, it is not to be expected that the working classes will escape these tendencies. On the contrary, materialism is almost the sole end of the socialistic or democratic movements of the day. Hence, then, it will be found in general in technical schools that those branches of study are most pursued which end in improved wages. This, though it may be regrettable, is to a great extent inevitable, and is not nearly as great an evil as at first sight appears. The best commencement for a young workman is a thorough understanding of the principles of his own trade. If ever he is to rise to higher things, it will not be by passing his own trade over, but through it and by means of it. The fortunate man whose lot lies neither in being a mere quill-driver on the one hand, nor a mere factory hand on the other, into whose life a little invention or art can enter, whether it be the laying out of a garden, the decoration of a room, the planning and laying on of gas and water, or any other trade that involves responsibility and thought, is surrounded with the mysteries of nature. They hem him in on all sides, and he can make no one step forward in any detail of his trade without having the opportunity of self-culture.

It remains only to add a few words upon the relation of technical schools to art. The art teaching of this country, which has been established among us for nearly half a century, has upon the whole been productive of great benefit, but our design is still very imperfect. Much—very much has been done in pottery, and much in fabrics and wall papers; a few really beautiful patterns are to be seen in almost every shop; but our silver work, our metal work, and our glass are, as a rule, beneath contempt from an artistic point of view, and our furniture is very poor. An especially hideous description of art seems to pervade all our cast work, whether in iron or brass; knockers, door-knobs, lamps, balustrades, chandeliers, gas brackets, tea and coffee pots, exhibit a wild jumble of Egyptian, Assyrian, Gothic, Greek, or Rococo, put together without taste or judgment. It is perhaps not quite so bad as the terrible specimens of a like nature which come from America, but s hopelessly inferior to similar art in France. The great work of our art classes in technical schools should be to remedy these defects; not to aim at high art as they almost invariably do, but to get out simple household articles of beautiful and ingenious patterns.

In the present days great efforts are being made in England to encourage the formation of technical institutes. Three or four new ones of large size have been established in London, and there are now few large towns which do not contain some kind of technical school. But it is of no use that these schools should be founded if those for whom they are intended do not take advantage of them. It is the duty of parents to see that their sons do so, and it is no less the interest than the duty of the employers to afford facilities to their apprentices to study in the evening. When one reflects how certain and large an increase of wages results from technical study, and how speedily those who pursue it rise in their trades, one can only be astonished at the folly and apathy of those who, for want of a little self-denial, throw away such solid and permanent advantages.

EXPERIMENTAL RESEARCHES ON ALTERNATE-CURRENT TRANSFORMERS.*

BY J. A. FLEMING, M.A., D.SC., F.R.S.

1. So much has been already written on the theory and performance of real and imaginary transformers that some excuse might seem necessary for venturing to add to the literature of the subject; and yet, when we come to review that which is absolutely accepted as settled truth with regard to transformers, we find acknowledged authorities were no long time ago, and perhaps are now, in entire disagreement with each other on matters which seem vital and fundamental. At the time when the investigations described in the following Paper were commenced, the matters in high dispute involved such practical questions as the relative superiority or advantages of open and closed magnetic circuits, the relative magnitude of the core losses at full and at no load, and the most trustworthy experimental methods of determining these transformer losses. During the many months that these experiments have been in progress, important contributions have been made to the solution of these question in Papers by Dr. Hopkinson, Prof. Ayrton, and Dr. Sumpner. Applying their own particular methods, they have reached conclusions on some of these points which it will be seen are similar to those arrived at in the following pages. As my own experiments, which were almost complete before these Papers appeared, have been made with apparatus and instruments obtainable in most electrical workshops, and have not been limited to one or two special transformers, but have been made with stock sizes of many different kinds and types of transformers, it seemed likely that they might have sufficient independent value to justify me in bringing them before you.

These experiments had their origin partly in my own desire for definite and trustworthy facts as to actual transformers in use, and partly arose out of an invitation of Mr. Swinburne to examine his "Hedgehog" transformer, and compare its performance with that of some closed magnetic circuit transformer of equal size. They have, however, gone beyond that last-mentioned aim; and it forms no part of my purpose to draw comparisons between transformers from a commercial point of view, but simply to record facts of observation and leave them to speak for themselves. As a matter of fact, it is a very difficult thing to institute exact comparisons between commercial transformers as made by different makers. In the first place, they take different stock sizes, and they design their instruments for different frequencies. Hence, if we procure stock sizes for experiment, they are not directly comparable. In the second place, if special sizes of equal output are specially made, the maker cannot generally do himself justice unless he has *carte blanche* as to price, and from a commercial point of view price is everything; and, lastly, as such experiments cannot be done all in a minute, but generally take many months to complete, the experimentalist finds himself often, when all is said and done, met by the progressive manufacturer with the placid remark, "Yes, but the transformer you have been testing is our *old* pattern; you have not seen the one we are making now." One of the objects of this investigation was to arrive at some definite certainty on the best practical method of quickly testing transformers in actual use and *in situ*. The particular methods employed by Dr. Hopkinson and Prof. Ayrton and Dr. Sumpner involve the possession of two transformers of equal size. These methods are in principle an extension to transformers of Dr. Hopkinson's method of measuring the efficiency of dynamos, and they are based upon the obviously right method of measuring directly the quantity we desire to know, viz., the power lost in the trans-

* Abstract of a Paper read before the Institution of Electrical Engineers on November 24, 1892.

Hosted by Google

former—rather than measuring it as the difference of two very much larger quantities, viz., the power going in, and the power coming out. These methods, as well as others which depend upon the graphic description of the current and electromotive force curves, have the disadvantage that it is often impossible to apply them, because only one transformer is at disposal, or because the observer has not access to the dynamo, and accordingly the first matter which engaged attention was an examination of the degree of accuracy to be reached by the simple direct methods which can be applied under such conditions as can generally be obtained in practice and when using the commercial instruments to be found or obtained in every testing laboratory.

I.—*Methods of Measurement Employed.*

2. In order that an opinion may be formed as to the confidence to be placed in the quantitative experiments described, it may be well to give, in the first place, some details as to the methods adopted for measuring the potential differences, currents, &c., and processes of calibrating the instruments used. These instruments were then employed in measuring the power taken up by transformers with open, or loaded, secondary circuits. As single transformers only of each type were at disposal, we entered on a preliminary investigation on the degree of accuracy to be obtained when using such methods as the three-voltmeter, the three-ammeter, and the two-circuit electro-dynamometer watt-meter of various constructions.

In order to avoid tedious repetitions, it may be observed once for all that when mention is made of "the current," or "the potential difference" of such and such an amount, the *effective* value is meant, or the square root of the mean of the squares of the equidistant instantaneous values, unless otherwise stated. The letters P.D. are used as an abbreviation for *effective* potential difference.

Mr. Swinburne placed at my disposal four of his electrostatic torsional voltmeters, and also two of his dynamometer watt-meters, and there were also at hand a sufficient supply of Kelvin current balances and electrostatic voltmeters and other appliances for the calibration of the above instruments. Since these Swinburne electrostatic voltmeters proved useful in much of the work, it may be advantageous to point out their good and bad points, and also to say how they were improved, calibrated, and used in these experiments. As they have been sufficiently described by their inventor, suffice it to say that they consist of two tiers of semi-cylindrical metal boxes, B (*see* Fig. 1), insulated from each other. A vertical metallic axis carries two semicircular aluminium "needles," set at different levels, so that one is enclosed in the upper pair of boxes and the other in the lower. This needle is strung at the top and bottom by a round phosphor-bronze wire 0·003 or 0·004in. diameter, and the top end of the upper wire is held by a torsion head, T, the indicating needle of which moves over a graduated scale. In most of the experiments these voltmeters were used as idiostatic voltmeters, and the "needle" and one pair of semi-cylinders formed one terminal of the instrument, and the other pair of semi-cylindrical boxes the other terminal. When a definite potential difference is made between the two terminals, the needle is displaced from its normal position, and the semi-circular needles attracted into the semi-cylindrical enclosing boxes, which are at a different potential. The upper torsion head is then turned until the needle comes back to its initial position. This is accurately determined by affixing a mirror to the axis of the electrometer needle. The image of the filament of an incandescent lamp is then thrown on the mirror by a lens, and, after reflection, received on a paper scale about one metre away. By a simple reference point on this scale it is easy to bring back the line of light accurately to its original position. In first working with these instruments we were greatly troubled by electrical discharges passing across from the "needle" to the cylinders and destroying the suspending wire by the resulting current. The simple remedy for this was found in enclosing each semi-circular aluminium disc of the "needle" between two thin sheets of mica which projected slightly over the edge of the sheet of metal. The instrumental utility of the voltmeter was not at all impaired, whilst at the same time discharges between the needle and enclosing boxes were prevented, and much labour thereby saved. The sensitiveness of the voltmeter was such that when used to read an alternating potential of 2,400 volts, a difference of 3 or 4 volts was easily detected, and with sufficiently steady potential there was no difficulty in taking the reading of about this number of volts to one-quarter per cent. accuracy. The great defect of the instrument as it stands is the large moment of inertia of the needle, and this, in the absence of any effective damping arrangement, creates a great waste of time in getting readings.

The instruments were provided with an electro-magnet intended to be used for creating a magnetic damping field. This, however, proved to be ineffective. A far better plan when such a heavy needle is employed is to damp out the oscillations by a suitable mica vane dipping in oil or water.

3. In calibrating these voltmeters, the first step was to prepare a standard inductionless resistance capable of carrying, without sensible heating, a current of at least a quarter of an ampere, and which could be subjected to an alternating pressure of 2,000 to 3,000 volts without risk of short-circuiting. This was formed by winding double silk-covered platinoid wire (No. 36 B.W.G.) round a wooden frame. The wire windings were each kept separate by being wound in serrations, or teeth, cut in the edge of varnished slate slips fixed at the top and bottom of the frame. The frames were about 37in. long and 14in. wide, and the wire made 56 turns round the frame, each turn of wire being separated by about a quarter of an inch from its neighbours. The length of wire on each frame was about 126 yards, measuring some 1,600 ohms. Six of these frames were provided, giving us, therefore, about 9,600 ohms resistance in the form of a wire perfectly insulated in every part and between every turn. This wire was capable of carrying about one-quarter of an ampere without any very sensible heating, and about three-quarters of an ampere without exceeding safe limits. Every part of the wire was accessible, and exposed to the cooling action of the air. The six frames were fastened up to the ceiling of the laboratory and arranged so that the direction of the wire windings was alternately right and left. The resistance of all these coils was measured when at 15°C., and found to be as follows :—

Coil 1	1,607·2	ohms.
„ 2	1,505·5	„
„ 3	1,525·5	„
„ 4	1,649·0	„
„ 5	1,610·1	„
„ 6	1,645·7	„
Total	9,543·0	„

On coil 1 two terminals were placed, one at a distance of 394·7 ohms from the end, and one at a distance of 1212·5 ohms from the end. By taking leading wires from these points it was possible to divide the whole resistance of 9,543 ohms into two sections, having in one case resistances in the ratio of 23·175 to 1, and in the other case a ratio of 6·87 to 1. This divided resistance was a practically

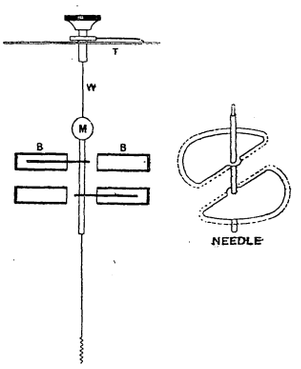

FIG. 1.—Diagram of Swinburne Voltmeter.

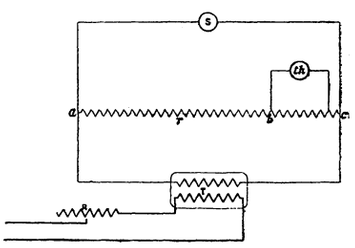

FIG. 2.—Plan of Connections used in Calibrating Swinburne Voltmeters.

non-inductive resistance of about 10,000 ohms, divisible into two sections in the ratio of 23 to 1 or 7 to 1. If a measured alternating pressure of 2,400 volts was applied to the ends of this resistance, the wire came to a steady temperature of about 20°C. to 25°C. above the atmospheric temperature (15°C.), as nearly as could be judged by a thermometer. Taking the coefficient of change of resistance with temperature for platinoid as equal to 0·021 per cent. per degree, it will be found that at 40°C. the whole coil would have a resistance of 9,591 ohms, and hence, if truly non-inductive, the current through the coil would then have a value of 2,400/9,591 ampere = 0·250 ampere. The actual current, carefully measured by a Kelvin deciampere balance, was found to be exactly 0·250 ampere, thus showing that the resistance was, for all practical purposes, non-inductive.

In all subsequent experiments it was therefore taken that when an alternating pressure of 2,400 volts was applied to this resistance, it passed a current of 0·25 ampere and absorbed 600 watts. This resistance will be hereafter called the "No. 1" resistance for reference. By the aid of this divided resistance the Swinburne voltmeters were easily calibrated.

A 24 to 1 transformer, T_1 (*see* Fig. 2), was connected to 100-volt mains through a rheostat R, so as to raise the pressure and enable it to be regulated within limits. The above standard divided resistance was placed across the high-tension terminals, and a Kelvin multicellular electrostatic voltmeter, Th, and a Swinburne electrostatic voltmeter, S, connected respectively to the small section and to the whole length of the resistance, as shown in Fig. 2.

Hosted by Google

By taking the readings of the Kelvin electrostatic voltmeter corresponding to various pressures and multiplying these readings by 24·175 we obtained values for the P.D. at the terminals of the Swinburne voltmeter, and hence the true values of the instrumental readings of the last-named instrument. For each Swinburne voltmeter a calibration curve was then prepared in which the horizontal abscissæ were the torsion-head readings, and the corresponding ordinates the true P.D. in volts at the terminals of the instrument. This curve (Fig. 3)* was found to be a very exact parabola. Having proved this to be the case by many experiments for each of the four Swinburne voltmeters, we subsequently adopted for each voltmeter an instrumental constant, the product of which by the square root of the torsion-head reading gave the terminal P.D. on the instrument. These constants were determined for each instrument at the beginning and end of every set of experiments.

In addition to the above standard resistance, another set of six similar coils was provided, each coil of which consisted of No. 32 B.W.G. platinoid wire wound in the same open manner on a frame. Each of these coils had a resistance of about 500 ohms, and each coil could carry comfortably, without any very sensible heating, about half an ampere. These last six coils were specially intended to be used for current measurement, as follows :—The coils were arranged either two, four, or all six in parallel, and the current to be measured passed through them. The P.D. at the ends of the compound resistance was measured by a Kelvin electrostatic voltmeter. The arrangement was standardised as an ampere-meter by passing known currents through the coils, measured by a Kelvin ampere balance, and then observing the P.D. at the ends of the compound resistance. In this way the true resistance of the coils grouped in various ways when carrying currents was found, and at any subsequent time the mere reading of the P.D. at the ends of the resistance gave the current passing through the coils. The reason for employing an electrostatic voltmeter and resistance in this way to measure current was that we thereby obtained an inspectional ampere-meter much more convenient in many experiments than an ampere balance or dynamometer. It will be seen, therefore, that all the measurements were ultimately referred to one Kelvin electrostatic voltmeter and one Kelvin deciampere balance. These instruments were found to agree with one another. Any other instruments, such as Siemens's dynamometers or an Ayrton and Perry twisted strip ammeter, sometimes used, were standardised and referred to the above-mentioned Kelvin balance, which was one specially constructed for alternating-current measurement.

This last-mentioned set of six resistance coils will be hereafter spoken of as the "No. 2" set. We frequently employed the No. 1 and No. 2 resistances in series, giving us a practically non-inductive resistance of about 12,000 ohms. The No. 1 resistance was also employed as an absorber of power. For if the six coils, each of about 1,600 ohms, were arranged three in parallel and two in series, we obtained an effective resistance of about 1,100 ohms, and this, when placed across a 2,400-volt circuit, passed a total current of rather more than 2 amperes, and absorbed about 5,000 watts. We found it very convenient to employ this resistance in this manner as a standard non-inductive power-absorber for obtaining the constant of various forms of wattmeter. Although using the No. 1 resistance in this way to absorb nearly 7-H.P., the current passing in each single wire was not more than two-thirds of an ampere, or well within the safe limits.

II —*Experiments with the Three-Voltmeter Method of Measuring Alternating-Current Power.*

5. Having the necessary instruments all calibrated and compared, a series of experiments was made with three or four of the Swinburne voltmeters, using them in accordance with the well-known method, for measuring the power taken up in transformers on open secondary circuit.

Two 5 H.P. transformers were arranged with low-tension coils in parallel on a 100-volt circuit, and high-tension coils (2,400 volts) in series (*see* Fig. 4). The current through the low-pressure coils could be varied by a rheostat, *f*, and hence the P.D. at the high-tension terminals of the transformers given any desired value from 2,400 volts downwards.

In the diagram (Fig. 4) T is a transformer in which the power taken up is to be measured; T_1 and T_2 are the 5-H.P. pressure transformers just mentioned. The torsion voltmeters. V_1, V_2, V_3, were arranged as shown; V_1 being across the terminals of the transformer to be measured, V_2 being across a non-inductive resistance, *r*, put in series with the primary coil of the transformer T, and V_3 used to measure the total P.D. between the outside terminals of the two pressure-producing transformers, T_1 and T_2. Since T_1 and T_2 were identical transformers, it was generally quite sufficient to measure the P.D. between the terminals of one transformer, T_1 or T_2, and to take double this P.D. as the value of V_3, except in cases where the total P.D. exceeded the limits of safety for one voltmeter, and then two voltmeters were used, one across the terminals of each transformer. Under these circumstances, as is well known, the power, W, taken up in the transformer, T, under test is given by the formula,

$$W = \frac{1}{2r_1}\left\{V_3^2 - V_2^2 - V_1^2\right\}.$$

In applying this method we had several difficulties to overcome before we could get any satisfactory results. In the first place, the transformer to be tested must have the potential difference, V_1, between its primary terminals always exactly maintained at the normal pressure, which, in all our experiments, was 2,400 volts. In the second place, the potential difference V_2 must always be made as nearly equal to V_1 as possible, in order to obtain the condition of greatest probable accuracy of measurement—that is, to obtain the condition in which given small percentages of error in the several voltmeter readings produce the minimum percentage error in the calculated power. In the third place, the resistance r_1 must be practically non-inductive, and must be capable of being varied in amount as required to fulfil the condition of making V_2 equal to V_1. We met these conditions in the following manner :—In cases in which the transformer T was not loaded on the secondary circuit, and in which, therefore, the current flowing through its primary circuit was not greater than could be comfortably carried by the No. 1 10,000-ohm standard resistance, we employed that resistance, arranging all six coils in series. In series with this we placed some or all of the coils of the second resistance, arranged in series or in parallel, and we placed a Kelvin voltmeter to read the fall in volts down one of these last coils. In other cases, when the transformer T was loaded up on its secondary circuit, and when, therefore, a larger current was flowing through its primary circuit, we employed a series of 24 50-c.p. 100-volt incandescent lamps, or several series of lamps in parallel, adjusted as required to obtain the requisite resistance. When these lamp resistances were used, the second (No. 2) set of resistance coils, arranged with 2, 4, or 6 in parallel, as necessary, were placed in series with the lamps. By measuring the fall in volts down this known wire resistance by a Kelvin electrostatic voltmeter, *th*, and the fall in volts over the lamps and resistance taken together by means of one of the Swinburne voltmeters, V_2, we were able to determine at any instant the value in ohms of this non-inductive resistance from the readings of two electrostatic voltmeters and the known value of the wire resistance across the terminals of the Kelvin voltmeter.

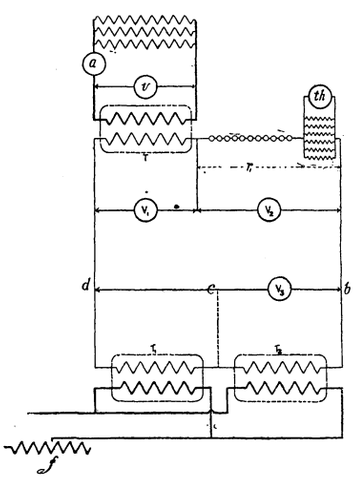

FIG. 4.—Plan of Connections for Three-Voltmeter Method.

The process of getting a reading was this : The resistance r_1 was varied suitably until the value of the P.D. V_1 was as nearly as possible equal to the value of the P.D. V_2. The feeding transformers T_1 and T_2 had a rheostat in their common low-pressure circuit, which was then varied until the P.D. V_1 came to the value 2,400 volts, and it was constantly maintained at that value. The reading of the other two voltmeters was then noted, as well as that of the Kelvin voltmeter Th. If we call A the ampere value of the current flowing through the primary coil of the transformer T, and, therefore, also that through the resistance *r*, it is obvious that the value of *r* is determined at once from the value of the P.D. V_3 and the value of the current A. A is, of course, known by the previous calibratiou of the Kelvin voltmeter and associated resistance as a non-inductive ampere-meter. Hence, if V_1 is constantly maintained at the value 2,400 volts, we see that the power W, taken up in the transformer, is given by the formula,

$$W = \frac{A}{2V_2}\left\{V_3^2 - (2{,}400)^2 - V_2^2\right\}.$$

If it had been possible to make V_2 also always exactly 2,400 volts, the formula would have been still more simplified.

* *See* original Paper.

Hosted by Google

It will be observed that we used a row or rows of 24, or less, 50-c.p. incandescent lamps as our non-inductive resistance, and determined the actual resistance at any instant by observing the terminal P.D. of the row of lamps, and the current flowing through them as measured by the fall in volts down a small known non-inductive resistance placed in series with them. We found this to be a better method than using any form of ammeter in series with the lamps—firstly, because we were more sure of not introducing prejudicial inductance into the lamp circuit; and, secondly, because we found we could obtain greater accuracy in the measurement of the current than by any other ammeter suitable for the purpose. The justification for using such a row of lamps as a practically non-inductive resistance is that if an incandescent lamp is placed in series with a dynamometer suitable for measuring both alternating and continuous currents, and if the terminal P.D. on the lamp is adjusted, say, to 100 volts as measured by an electrostatic voltmeter, no sensible difference can be found in the current as measured by the dynamometer, whether that current is alternating or continuous.

It will be seen that when the transformer under test is loaded on its secondary circuit, in addition to the ammeter and voltmeter measurements necessary to estimate the secondary load, we have four, and sometimes five, other voltmeter measurements to make simultaneously in order to get one observation of the power absorbed in the transformer. In dealing with the mere theory of an experimental method, nothing is easier than to say "Let V be a constant P.D."; but in actual practice, and when working off the mains of existing public electric supply companies, this ideal condition is very difficult to realise, and the observers have their patience strained often almost up to the safe working limits to obtain any results worth having at all. We found that the multiplicity of readings to take simultaneously constituted a very great drawback to the utility of this voltmeter method. Having the apparatus, however, set up, and the instruments all calibrated, the method was applied to measure the power absorbed in a number of transformers with open secondary circuits, and in one or two cases the power taken up in the transformer corresponding to various secondary loads was also taken.

6. The results of some of these observations are given in the fourth column of Table I., in which the determinations of the power-absorption of various transformers at no load obtained by different methods are collected. In this table the first column gives the maximum output in watts of the transformer; the second gives the "magnetising current," or primary current, at no load; the third the primary volts, or P.D. at the primary terminals; the fourth, fifth, sixth, and seventh columns give various power determinations; the eighth gives the "apparent watts" absorbed at no load, or the numerical product of magnetising current and primary volts; and the ninth column gives a number which it is convenient to call the *power-factor* of the transformer at no load—it is the ratio of the *true* to the *apparent* watts. If the currents and pressures were simple sine functions, then the power-factor in that case would be the cosine of the angle of lag of primary current behind the primary terminal potential difference.

In criticising these results, it must be borne in mind that several of the transformers were intended to be used at a frequency of 100, and not at 83, and that therefore comparisons between the resulting numbers are not to be instituted without regard to this circumstance. As an example of a series of voltmeter tests, the details of the observations on a series of transformers at no secondary load are given in full in Table II. of the Paper.

7. The application of the three-voltmeter method to closed magnetic circuit transformers, or transformers with large power-factors at no load, showed that it was possible with care to obtain very fairly good power determinations agreeing well with one another; although the number of instruments to be read rendered it exceedingly difficult, unless the pressure was absolutely steady, to get the benefit of the full possible individual accuracy of each instrument. The moment, however, that we turned attention to transformers with small power-factor, such, for instance, as the Swinburne "Hedgehog," the difficulty of obtaining very consistent results was considerably increased. The reason for this is fully explained in a Paper by Prof. Ayrton and Dr. Sumpner, "On the Measurement of the Power given by any Electric Current to any Circuit" (*Proc.* Roy. Soc., London, Vol. XLIX., p. 434, 1891).

Assuming currents and potentials to vary harmonically, they show that if the same percentage error, e, is made in reading each voltmeter, the percentage error in the calculated power will be

$$\sqrt{\frac{2+4(1+\cos\phi)^2}{\mathrm{Cos}^2\,\phi}}$$

times e, where cos ϕ may be approximately taken to be the same quantity as that which we have above called the *power-factor*. Hence, if $e=1$ and cos $\phi=0{\cdot}75$, the multiplier is found to be 5; but if $e=1$ and cos $\phi=0{\cdot}06$, then the multiplier is 40. In other words, a uniform error of 1 per cent. in the voltmeter readings makes only 5 per cent. error in the power when operating on a closed-circuit transformer; but a 1 per cent. voltmeter error means a 40 per cent. error in the power when testing a "Hedgehog." Hence, unless the very greatest constancy in the alternating pressure can be obtained, the three-voltmeter method will not give good results when applied to an open magnetic circuit transformer. In order to show the extent of variation of the power determinations from the mean value, when applying the three-voltmeter method to a "Hedgehog" transformer on open secondary circuit, the individual values obtained on different occasions are grouped together in Tables III. and IV.

Power in watts absorbed by Swinburne "Hedgehog" transformer (3,000-watt) at no load. Taken by the three-voltmeter method. R=3,297 ohms; power-factor, 0·088; apparent watts taken up at no load, 1,752.

Third Set. Frequency = 83·2 ∿; magnetising current, 0·765 ampere.

* The power determination by the three-voltmeter method, viz., 126 watts, was made on one transformer, No. 1,952. The power determination by the dynamometer, viz., 140 watts, is the mean of four values obtained on another transformer, No. 1,868, one value of which is also 126 watts.

Hosted by Google

In the first set of observations (Table III.) R was kept constant and the values of V_1 varied slightly; in the second and third set (Table IV.) V_1 was kept absolutely constant, and R was adjusted to make this the case. In the third set the conditions for greatest accuracy were best obtained, V_1 being kept constant, and V_2 made as nearly as possible equal to V_1 by varying R as required. The mean value of the power absorbed by the open-circuit "Hedgehog" in these experiments was respectively 155, 101, and 85 watts at no load. The mean of the means is 114 watts. The mean of all the 30 determinations made with the three-voltmeter method is 112 watts. This is, therefore, the mean result for the power in watts absorbed by the 3,000-watt "Hedgehog" transformer on open secondary circuit when worked at a frequency between 83 and 88. The greatest value of the watts is 171, and the least 64; and the greatest deviation from the mean is 49 watts, or, roughly, 50 per cent. The transformer was marked by the maker to be worked at 100 periods per second. We used it at 83 to 88. It appears, therefore, that, owing to the low power-factor of this transformer, it is a bad subject for the three-voltmeter method, and that even with the greatest precautions considerable deviations from the mean may occur in making a series of power measurements in its case. Nevertheless, it will be shown later on that there is reason to believe that the mean value so obtained of the power absorbed at no load, viz., 112 watts, is not far wrong.

8. As regards the three-voltmeter method itself, considered as a practical method of measuring alternating-current power, the following conclusions were impressed upon us:—(1) It is only applicable in cases when a very steady alternating pressure can be obtained of the requisite amount, and it is therefore unsuitable in general for working as a workshop method, or off commercial alternating circuits. (2) Owing to the number of instruments to read, it is difficult to carry it out as a practically useful method without the assistance of several observers. (3) It is especially difficult, if not impossible, to get good results with it when applying it to test transformers of open magnetic circuit type, and having, therefore, a small power factor. (4) Unless all the conditions for maximum accuracy can be secured, owing to the nature of the formula for the calculation of the power, the results will not be very trustworthy.

9. In applying the method to measure the power taken up in the primary circuit of a transformer when the secondary circuit is loaded up, the non-inductive resistance R must be capable of passing the full primary current required, and yet be capable of being so adjusted that at each stage of the load the fall of volts, V_2, down this resistance, is approximately equal to the pressure, V_1, on the terminals of the primary of the transformer being tested. It is essential that this last condition shall hold good, or else we do not obtain the same probability of accuracy in the calculated value of the power given to the primary circuit at all loads. It was found, therefore, that the most convenient arrangement to employ for the non-inductive resistance was one or more parallel series of incandescence lamps. We employed one series of 24 50-c.p. 100-volt lamps, and two series of 24 16-c.p. 100-volt lamps, the three series being arranged in parallel when required, and any required number out of the 24 lamps in each series taken. In order to measure the resistance at any instant of this bank of lamps, the second set of six non-inductive resistance coils was arranged in series with the lamps, and the drop in volts down this known resistance measured with the Kelvin electrostatic voltmeter. This gave us the current flowing through the lamps, and the Swinburne voltmeter gave us the P.D. over lamps and resistance. Hence, knowing the terminal P.D. and the current, we have the value of the non-inductive resistance r_1 at any instant given by the inspection of two voltmeters. In making the full test at all loads of a transformer by this method, the power given out from the transformer was taken up on a bank of incandescent lamps, and the current and terminal volts measured by a Kelvin balance and Kelvin multicellular electrostatic voltmeter. The results of a double series of observations on a Ferranti 5-H.P. 1885 (old form) transformer, and those on a Swinburne 3,000-watt "Hedgehog," are tabulated in Tables V., VI., VII., and VIII.

In these tables the first three columns give the volts, current, and watts output, W_2, of the secondary circuit; the fourth column gives the primary current; the fifth, the value of the inductionless resistance in series with the primary; the sixth, seventh, and eighth columns give the values of the voltameter readings, V_1, V_2, and V_3; the column headed W_1 is the calculated value of the power given to the primary circuit; the last two columns give the value of $W_1 - W_2$, or the total power in watts absorbed in the transformer, and the ratio W_2/W_1, or the efficiency, expressed as a percentage. The values of $W_1 - W_2$ are the total power in watts dissipated in the transformer, partly as copper frictional losses (C^2R losses), partly as iron losses (eddy-current and hysteresis), and in any other way, such as eddy currents in the copper circuits by which internal work is being expended.

Table V.—Ferranti Transformer (1885 *pattern*).—No. 747. Power=5-H.P. Secondary volts=100. Frequency used, 81·7 periods per second. Average final temperature of transformer, 212°F. Volts on primary circuit (V_1)=2,400 (kept constant). Primary circuit resistance=12·50 ohms at 212°F. Secondary circuit resistance=0·0252 ohm at 212°F.

[Table V. shows that the primary amperes rose from 0·336 to 1·516. The secondary amperes rose from 0 to 30·07, the secondary volts fell from 100·4 to 99·2. The total power taken up in the transformer rose from 516 to 571 watts.]

Table VI.—Ferranti Transformer (1885 *pattern*).—No. 747. Power=5-H.P. Secondary volts=100. Frequency used, 84·8 periods per second. Average final temperature of transformer, 212°F. Volts on primary circuit (V_1)=2,400 (kept constant). Primary circuit resistance=12-50 ohms at 212°F. Secondary circuit resistance=0·0252 ohm at 212°F.

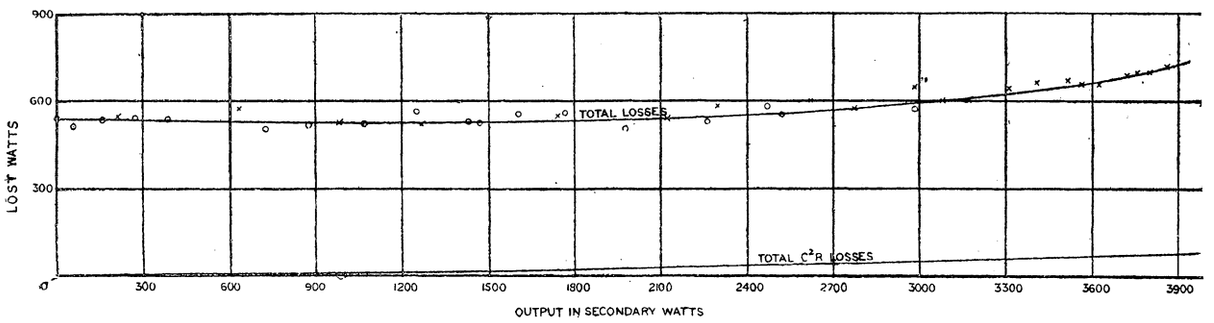

FIG. 5.—5-H.P. (1885 Pattern) Ferranti Transformer. Losses by Three-Voltmeter Method.

[Table VI. shows that the primary amperes rose from 0·329 to 1·9. The secondary amperes rose from 0 to 39·19, the secondary volts fell from 100·9 to 98·5. The total power taken up in the transformer rose from 509 to 720.]

Table VII.—Swinburne "Hedgehog" Transformer.—No. 342. Power=3,000 watts. Secondary volts=100. Frequency used, 83·7 periods per second. Average final temperature of transformer, 147°F. Volts on primary circuit (V_1)=2,400 (kept constant). Primary circuit resistance=24·00 ohms at 145°F. Secondary circuit resistance=0·051 ohm at 145°F.

[Table VII. shows that the primary current rose from 0·738 to 1·578. The secondary amperes rose from 0 to 30·1, and the secondary volts fell from 102 to 99. The total power taken up in the transformer varied between 81 and 209.]

Table VIII.—Swinburne "Hedgehog" Transformer.—No. 342. Power=3,000 watts. Secondary volts=100. Frequency used, 82·3 periods per second. Average final temperature of transformer, 145°F.

[Table VIII. shows that the primary amperes rose from 0·76 to 1·566. The secondary amperes rose from 0 to 29·93, and the secondary volts fell from 102·1 to 98·8. The total power taken up in the transformer varied between 0 and 237.]

In Fig. 5 is shown a curve representing the values of $W_1 - W_2$ for the Ferranti 5-H.P. transformer, taken from the results in Tables V. and VI. The secondary output of the transformer in watts is set off on the horizontal line, and the vertical ordinates of the upper curve are the corresponding values of the "total lost watts," or total power losses in the transformer at these various loads. The lower curve is the curve of total copper (C^2R) losses, taking both primary and secondary together. The difference between the ordinates of the upper and lower curves represents the power lost in the transformer in iron losses and eddy-current

Hosted by Google

copper losses, if any. It is seen that the upper curve keeps roughly parallel to the lower curve, and that, therefore, as far as these observations go, there is no indication that the core losses get less as the output increases; on the other hand, they seem to get slightly greater. It is much more convenient and instructive to plot out in this way a "total loss curve" for the transformer than to plot an efficiency curve, for if an accompanying $C^2 R$ curve is drawn it shows us at once what is the magnitude of the total eddy-current and hysteresis losses to be accounted for. The values of $W_1 - W_2$ for the Swinburne "Hedgehog" given in Tables VII. and VIII. are found, when plotted, to lie so irregularly that an exact determination of the total loss curve by these tables is impossible. The power-factor of the "Hedgehog," even at full load, is still small, and we were not satisfied with the general nature of the results given at all loads by the three-voltmeter method for this transformer. In the case of the Ferranti 5-H.P. transformer (1885 type), the determinations of the power taken up at no secondary load were fairly consistent. The mean value is 520 watts. The mean of all, corresponding to a frequency of about 83, is probably close to 540 watts, as given in Table I.

(To be continued.)

ELECTRIC MOTORS IN FACTORIES.*

BY R. H. HOUSMAN.

The problem of obtaining the power for driving machinery at the least possible cost is one which meets with solutions varying with the circumstances of each particular case and the taste of each particular engineer.

The case most favourable to economy may be typified a Lancashire cotton mill, in which the whole work is concentrated in a single building, and the demand for power being nearly constant it is supplied by a single large engine working under the most efficient conditions, and distributed to the machinery by gearing, ropes and belts, with a minimum of loss on the way. It seems hardly possible to improve on such a system as this except in detail. Directly, however, these ideal conditions are departed from by distributing the work amongst a number of buildings there is a considerable choice of methods for distributing the necessary power. In certain cases the buildings may all be connected by rope or other gearing, and so be driven from a single engine, but in many cases this is impracticable. It then becomes necessary to have a separate engine in each building supplied with steam, either from a central battery of boilers or each from its own boiler, and here the loss of economy begins.

When steam has to be carried considerable distances, however carefully the pipes may be lagged, not only is there the direct loss due to condensation, but also a further loss from the decrease of efficiency of the engine induced by the supply of wet steam, which loss may reach 20 per cent. or so. On the other hand, where each engine has its own boiler, the efficiency of labour is much reduced by the employment of a separate stoker, whose time is only partly occupied.

There is a further loss due to variation of demand for power, causing the engine to be alternately over and underloaded, and the chance of this increases as the building becomes smaller.

Added to all this is the comparative inefficiency of smaller engines, which are most likely to be worked non-condensing when scattered about promiscuously. Under these unfavourable conditions the cost of power may be many times greater than in the first case.

Electric Plant.

We will now consider what degree of economy is attainable when one or more large engines are used to drive dynamos generating the current which is distributed by copper conductors to motors which supply the necessary motive power. It is evident at first sight that the combination of a dynamo, a conductor, and a motor is rather an expensive form of coupling, which would not be employed in a cotton mill to take the place of ropes or gearing except by a most enthusiastic student of electrical engineering. It is, however, the peculiar advantage of the electrical system of distribution that it makes very little difference to the cost of power whether the work is all concentrated in a single building or scatterred over an area of several acres, so that it is possible under the most unfavourable conditions to keep the cost of power delivered to the machinery within measurable distance of the corresponding cost in a cotton mill.

In order to approach as nearly as possible to this high standard of efficiency, the condition of the working of a large mill engine must be applied to the generating plant as closely as possible. The most essential points are:—

1. Concentration at a single centre, so as to economise the labour of attendance and stoking as much as possible. It may be taken that in a properly designed generating station not more than one attendant to each thousand horse-power is required, since the main point is vigilance to detect incipient trouble, and it is difficult to find the men work enough to keep them on the alert. At the same time, the machines must not be so crowded together as to obstruct free passage or free view from one to the other. Where belt-driven machines are used the engines and dynamos should be kept on different sides of the station, and not mixed up together. In most cases, however, direct-driven dynamos are far preferable.

2. Working of the plant at or near its full capacity. It is on this account generally necessary to abandon the ideal simplicity of one large engine and one large dynamo, since the amount of power required may vary from time to time with the state of trade, &c. It is not, however, necessary to subdivide to the same extent as in an electric lighting station, and if the total power is divided among three or four equal-sized sets it will in general enable the load to be kept within the economical limits. The effect which partial loading has on efficiency will be noticed later on.

Variation of Load.

Since the efficiency of the system depends to a great extent on keeping the plant fully loaded, it is necessary to consider within what limits the load may from time to time vary.

In the case of a shop containing a large number of machines, such as lathes, for example, the power required will only vary slightly from minute to minute, since the number doing actual work at any moment is on the average nearly constant.

The ratio of the maximum demand for power, and that required to run the machines light, depends a great deal on how hard you can persuade the men to work. There is a notable difference when they are on piece-work or some profit-sharing system, instead of being employed by the hour. Under favourable circumstances the useful work may reach 70 per cent. of the whole, but it is often much less. It may therefore be taken that for work of this kind the ratio of maximum to minimum load will not exceed 3 to 1.

Sudden Variations.

There is quite another class of work represented by such operations as rolling, tube-drawing, lead-squirting, &c., in which the fluctuations of load are very violent, and the ratio of maximum to minimum may be as high as 20 to 1.

In cases where the maxima are of short duration (not exceeding half a minute or so) the excessive demand may be supplied by a fly-wheel of suitable capacity, without any great variation in the current supplied to the motor, which should be designed to slow down about 30 per cent. between no load and full load, so as to allow 50 per cent. of the energy stored in the fly-wheel to be utilised. In this way, during the intervals between the heavy loads, the motor is profitably occupied in increases to speed of the fly-wheel up to a certain limit that it cannot pass, and thus, on the average, works under fairly economical conditions.

When the maximum demand for power is of greater duration than about half a minute, it is no longer practicable to depend on fly-wheel storage, and the motor must be capable of meeting the heaviest of the load without injury. In this case, the full variation of load falls upon the generating plant, but is only troublesome when the latter is working close to its maximum output, or when the variation is a large fraction of the whole load. Under either of these circumstances ample fly-wheel capacity on the engine is of great assistance; but it must very much exceed the usual allowance to be of any use. If the mean velocity of the rim is 100ft. per second, each hundredweight of metal in it only stores about $\frac{1}{2}$ H.P. min. (17,000ft.), and as the speed should not vary more than 5 per cent, only 10 per cent. of this energy is available; thus each ton can supply 1 H.P. min. without exceeding the given variation of speed.

A more perfect but less simple way of dealing with sudden variations of load is by using a battery of secondary cells in parallel with the generating dynamos, so as to supply current as soon as the volts fall a little below the normal. The main objection to this is the trouble and expense that at present hang round a battery; perhaps some day this objection will vanish.

Efficiency of Engines.

It is now generally realised that overloading an engine is much less prejudicial to its economy than underloading it. It was once thought that automatic expansion secured economy for small loads; the fact is, however, that at a certain point initial condensation counterbalances the gain due to increased expansion, and the writer often proved by experiment that large compound-condensing engines take at least 20 per cent. more steam when running light with instantaneous cut-off than with moderate expansion and low steam chest pressure, and this is independent of the increase of

* Paper read before the Mason College Engineering Society.

Hosted by Google

indicated horse-power due to high initial stresses and of the superheating due to throttling. In fact, automatic gear is valuable, chiefly because it allows the *overloading* of an engine at times of excessive demand—that is to say, for increase of output rather than of economy.

Efficiency of Motors.

It is now necessary to consider the efficiency of motors when fully and partially loaded. Taking the case of a shunt-wound motor of most approved design, giving 40 B.H.P. at 600 revolutions, the various losses in it are as follows :—

Magnet excitation	1·5%	of full load
Hysteresis and Foucault current	2·5%	„ „
Sum of constant loss	4 %	„ „
Loss in armature full load	2 %	
Total loss at full load	6 %	

or commercial efficiency = 94% at full load.

At half load constant losses	= 8 %	of half load
Armature loss at half load	= 1 %	
Total loss at half load	= 9 %	

Commercial efficiency = 91% at half load.

At quarter load constant losses	= 16 %	of quarter load
Armature loss	= ½%	
Total loss at quarter load	= 16½%	

Commercial efficiency = 83½% at quarter load. At no load the waste is only 4% of full output.

These figures, though higher than those usually attained, are quite practicable. The efficiency of smaller motors is lower and of larger ones slightly higher than the above. It may therefore be taken that 90 per cent. efficiency is easily realised under working conditions, provided that the motors are of fair size.

Willans' Experiments.

Without attempting to go over the whole ground covered by Papers which every engineer should study in the original, the results which bear most on the subject of the present Paper are that a good non-condensing engine consumes about one-third of the steam when running light as when loaded to a mean effective pressure of 45lb. per square inch, that for a given ratio of expansion each additional horse-power coils the same amount of steam. If the same engine is used, condensing the consumption at no load is reduced to about one-half, but each additional horse-power still coils the same amount as when non-condensing. Thus, the chief gain in condensing is for small loads, though it is still 15 to 20 per cent. at full load. The figures given are for high-speed Willans' engines, in which the cylinder condensation is comparatively small, but the same general law applies in all cases.

In some experiments made by the writer on a 200 H.P. compound-condensing engine of usual type, running about 800 revolutions, the consumption when running light was fully one-fourth of that at full load ; but each additional horse-power cost the same amount of steam when the cut-off was kept constant and the pressure varied by throttling, which in this particular proved to be the most economical form of governing, since the latest cut-off obtainable (about one-third in high-pressure cylinders) was the most economical for all loads. The writer has also found the same law to apply to an Otto gas engine, the consumption when running light being about one-fifth of the maximum, and the B.H.P. can be accurately measured by counting the explosions per minute and subtracting the number required to run light.

Efficiency of Generating Plant.

As the advantages of direct driving of the dynamos are so great as to practically exclude any other method where space is of any value, and as it is only with this class of plant that any accurate systematic tests are made, the figures obtained in every-day trials of Willan's engines combined with dynamos of various types may be taken as a standard. According to these, with engines of 100 H.P. and upwards, 15lb. of steam per 1 H.P. at full load, with 150lb. pressure, and condensing is easily obtained. At full load about 85 per cent. of the 1 H.P. appears as E.H.P., and at half load 75 per cent. ; under working conditions 80 per cent. may be taken as a fair average ; of this a certain amount is lost in the conductors connecting dynamos and motors, and there is a further loss in retransformation in the motors ; but unless the distance to which the current is conveyed is great, or the motors are of small size, this loss should not exceed 12 per cent. Thus, about 70 per cent. of the original H.P. appears as B.H.P. on the motor shafts ; this represents a cost of between 21 and 22lb. of steam per B.H.P. hours.

General Requirements of Factory Motors.

In order that the full benefit of concentration may be obtained it is absolutely essential that the motors should run without attention or "nursing" of any kind. It is, therefore, necessary that no adjustment of the brushes should be required with varying load. Perhaps the simplest way of attaining this is by the use of carbon brushes either alone or combined with copper ones, but even this is not sufficient to counteract the effects of bad design. A machine that will not keep its commutator smooth should have no place in a factory, as it is a constant source of trouble and expense.

Another difficulty often experienced with motors is the speed that they run at, often 1,000 revolutions and upwards. This means generally either an extra countershaft or a very small pully. It is evident that a 3ft. pully running at 300 revolutions is much better for the belt than a 1ft. pully running at 900 revolutions. It is about time that these slower speeds became more general, since they are quite practicable with multipolar machines.

In conclusion, it may be said that the general advantages of electrical distribution are, first, the ease with which power can be applied at any point required over a wide area at a cost not much exceeding the cost of power in a Lancashire mill, and secondly, the flexibility of the system which enables it to meet great variations in the power required without loss of economy. The main drawback is that as a means of merely transmitting power the first cost is high (compared with rope transmission, for example), but in many cases where other methods of transmission from a single centre are impracticable, the difference in the costs of labour and fuel of the "scattered small engine system" would very soon pay for the cost of electrical plant.

A PACIFIC CABLE.

[From *The Times*, November 18.]

In November, 1872, public banquets were held in London, Adelaide, and Sydney in celebration of the completion of the grand electric chain which united the capitals of the Australian colonies with the rest of the British Empire. Twenty years later proposals have been submitted, in a form which seems to imply serious business, to construct an alternative service to Australasia, *viâ* the Pacific. The idea has, of course, been long mooted. Queensland has never been reconciled to the construction of the land line of 2,000 miles through the heart of Australia by the splendid enterprise of South Australia, which, at a cost of nearly half a million sterling, connected Adelaide with Port Darwin, the terminus of the Eastern Extension Company's cable system. Queensland was ambitious to construct the land link with the Company's cable, *viâ* the eastern coast and Cardwell, to the Gulf of Carpentaria. But the energy of South Australia, combined with the ignorance which prevailed as to the route from Port Darwin to the Roper River, induced the Company to give the preference to the project of the southern colony.

The idea of an alternative cable, *viâ* the Pacific, has long exercised a fascination over the minds of certain enterprising gentlemen in Canada and England. The Pacific Telegraph Company was accordingly registered, with a nominal capital of £2,000,000. Though this was not subscribed then or since, the Company submitted proposals to the Colonial Conference which assembled in London early in 1887 for the construction of a cable from Vancouver Island to Australia, touching at Hawaii, Fanning Island, Samoa, Fiji, and New Zealand ; and, in return for a guarantee from the Governments of Great Britain, Canada, and the Australian Colonies, of traffic to the amount of £75,000 per annum for 25 years, they agreed to grant a cable rate of 4s. per word for both Government and public messages, and to make further reductions if the estimates of increased traffic were realised. A general assent was given by the Conference to the importance of cable communication between Australia and Vancouver, but the proposal has not advanced much beyond the region of discussion. Mr. Sandford Fleming, C.M.G., of Canada, has been one of the strongest advocates of the alternative line, largely on the ground that it would pass mainly through British possessions.

But the proposals which are now made, and which seemed destined to bear fruit, are of French origin. The negotiations with the Colonial Governments consulted have been conducted through Captain Audley Coote, who, on behalf of the Société Française des Télégraphes Sous-Marins, has undertaken to lay, within 18 months, a cable establishing communication between Queensland and New Caledonia. In making his proposals to the Hon. T. Unmack, the Postmaster-General of Queensland, Captain Coote distinctly declared that the new line would be the first section of the main Pacific Cable that Queensland and Canada were so anxious to have completed. The two colonies which must primarily benefit from the construction of the line to New Caledonia are Queensland and New South Wales, the former being only 900 miles distant and the latter having already extensive commercial relations with the French penal settlement. The Governments of these colonies appear to have readily acquiesced in the proposal that they should each guarantee the French Company £2,000 a year on condition that the French Government guaranteed

Hosted by Google

£8,000 a year for 30 years; the Company, in their turn, undertaking to lay, maintain, and work the line, allowing the guarantors the free use of the section for Government messages up to the extent of their guarantee in each year of the period referred to. It was further agreed that the working expenses should not exceed £2,400 a year, and that the receipts over and above that amount should go towards the annual reduction of the guarantee of £12,000, to be shared at the rate of one-sixth for Queensland, one-sixth for New South Wales, and two-thirds for the Government of France. The cable rate between Queensland and New Caledonia will be 6s. for a ten-word message and under (including address and signature), and 6d. extra for every additional word. Though the matter has been kept decidedly quiet, considering the magnitude of the political and commercial interests involved, confirmation has been obtained in Paris of the accuracy of the above details. The French Government admit that they are parties to the contract, and it is anticipated that the guarantee of £8,000 a year will be ratified by the Chamber of Deputies next month, and very possibly the Submarine Company will receive other help from them besides. But in any event the Company have sufficient faith in their enterprise to proceed with it whether the French Government assist them or not. Indeed, they have authorised Captain Coote to announce their willingness to continue succeeding sections of the main Pacific cable with all possible dispatch. They are even ready to begin to lay the Fiji section at the same time as the line to New Caledonia if a guarantee can be arranged, and also to couple up the Hawaiian Archipelago. With commendable foresight, Captain Coote, when he first thought of constructing a Pacific cable, arranged with the Hawaiian Government to grant him an annual subsidy of $25,000 for 15 years, provided communication were established between Honolulu and "some point on the North American continent or elsewhere" not later than the first day of January, 1894. Presumably that agreement can be modified, as also that by which Malietoa, King of Samoa, in 1884, granted Captain Coote the exclusive right for 21 years to lay cables into and out of that archipelago, for 21 years from the time the cables are first landed. Much has happened to Malietoa Pupu since he signed that agreement, and possibly the protecting Powers would require to be consulted before it would be recognised.

It was at first thought that either Sandy Bay or Cape Moreton would have proved a convenient starting-point for the Queensland end of the Pacific cable, but it has been found that neither of these positions offer such advantages as the Burnett Heads, which supply a sheltered position and a good landing. Though it is hoped that Vancouver will prove to be the other terminus of the cable, there is nothing so far to prevent San Francisco, or any other point on the North American continent being decided on. So far as the wider scheme is concerned, it is open to doubt if the French Government can be considered in any sense parties to it. They have long felt the inconvenience and danger of being isolated from so important a colony as New Caledonia, and are willing to pay handsomely to have the want supplied; but they would probably open their eyes if they were asked to commit themselves to the heavy additional responsibilities which must be faced by some Governments before the main Pacific cable is likely to be constructed. Colonial statesmen are not blind to the disadvantages incidental to the cable touching at French territory, but they seem disposed to pass them over. The Hon. T. Unmack, when referring to the subject before a recent inter-colonial conference, said he did not think they need trouble themselves much about that question, because, first of all, they had seen how territories frequently changed hands, and as far back as 1884 they would find a treaty of nations by which they bound themselves that all cables in time of war should be considered as neutral. The route, according to Mr. Unmack, would be first through New Caledonia, then Fiji, Samoa, Honolulu, the Fanning Islands, and probably either Vancouver or San Francisco; but, whatever route was adopted, he pointed out that the line must pass through some countries where the British Government was not supreme.

LEGAL INTELLIGENCE.

Hopkinson v. The St. James's and Pall Mall Electric Lighting Company (Limited).

The hearing of this action was resumed on Tuesday last before Mr. Justice Romer, in Chancery Court III.

After a brief further examination by Mr. FINLAY, Mr. J. D. F. Andrews was cross-examined by Sir RICHARD WEBSTER: Witness stated that he was first asked about his supposed anticipation of the three-wire system about four weeks ago by a gentleman who called on him from Messrs. Siemens Brothers, whose name he did not know. He drew the diagram (J.D.A. 1, see *The Electrician*, November 11th, p. 47) on Saturday afternoon, November 5th. He was quite alone. He drew a preliminary one himself, which was not in Court. He was a patentee of an improvement of the three-wire system. Between leaving the works at Glasgow and his recent conversation he had never drawn or described the Glasgow wiring to anybody. The gas engine was, to the best of his recollection, of eight-horse. He would undertake to say that it was not two-horse nominal, working up to 3½-horse actual. If all the lamps shown in diagram were in use at the same time, more than 2½ H.P. would be required. There were never more than 20 lamps on. There were gas fittings all over the shop for gas lighting. The workmen's benches were lit by gas in the ordinary way. He never finished a glow lamp there fit for sale. He was the patentee or inventor of an improved arc lamp—a "plate" lamp. His experiments at Glasgow did *not* consist partly in trying to run two "plate" lamps in series. The trials with "plate" lamps in series were at Siemens Brothers. If the Glasgow machine had come to him with the circuits parallel, he could not have got the double voltage. It came to him with the coils in series.

Sir RICHARD WEBSTER: I think you are mistaken. Just listen to your own letter:—"We were sorry to find the two circuits of the W. 3 you have just supplied us were connected in opposition, and so neutralised each other, and this caused us some delay in our experiments, it being necessary to take out the armature and reconnect it. It also proved that the machine could not have been tried before leaving your works."—That letter was written under a misapprehension, and I discovered it soon after I post d the letter.

Whatever it was, as a matter of fact, did you desire to have a machine in series?—I did.

Was not the object of having the machine in series that you would have, we will call it, positive at one terminal and negative at the other terminal, so that you could get a less voltage by using one-half of the machine independently?—Yes, that was the case.

Do I understand you to say that you always knew that you had used this three-wire system publicly in Glasgow?—Yes, always.

Did you yourself apply to Dr. Hopkinson for a licence under this very patent for the three-wire system?—Yes I did.

Do you represent to my Lord that when you applied for this licence under Dr. Hopkinson's patent you knew at the time that there had been a public user of it?—Yes, I did.

Did you endeavour to get the best terms you could to be sole licensee of Dr. Hopkinson's patent?—Yes, of a certain application of it.

Did you see both Mr. Belfield and Mr. Scanes, and I think Mr. Baldwin?—Yes, I saw those gentlemen on the subject.

WITNESS, continuing, stated that the patent referred to was for putting three conductors round one another with insulating material in between. He had not advertised it, but had announced it publicly.

Sir RICHARD WEBSTER: Did you see Mr. Belfield, Mr. Scanes, and Mr. Baldwin, and did you say to all those gentlemen that unless you could get a licence under Dr. Hopkinson's patent your patent would be worth nothing?—I think I did. It is very likely that I would.

After reading some correspondence which had passed between Mr. Andrews and Dr. Hopkinson and the Westinghouse Company with reference to a licence, Sir Richard Webster, continuing his cross-examination, said: Did you at that interview with Mr. Belfield, or Mr. Scanes, or Mr. Baldwin make the slightest suggestion that the Hopkinson patent was invalid?—Yes, I did.

What did you say?—I said I knew of instances where the three-wire system had been used.

Where?—In Blackpool.

Did you say a word about Glasgow?—No.

You, I suppose, used that in order to try and get better terms?—No, I did not.

Why did you do it, then?—We were having a general conversation—a pleasant conversation.

You asked the Westinghouse Company to help you to bring out a company, I think?—Yes.

WITNESS, continuing, said he had no desire in 1882 to get Mr. Graham, Mr. Rankin Kennedy, Mr. Bottomley, or Lord Kelvin to assist him, or to assist his Company, in bringing out new electrical inventions, or in promoting other business. These gentlemen came and inspected the workshop, though he did not recollect seeing Mr. Rankin Kennedy there in the early part of 1882. He did not know whether Mr. Rankin Kennedy ultimately purchased the plant that was in that place, nor remember the number of the dynamo.

Sir RICHARD WEBSTER: On the last occasion, you know, you said that you bought it back from the Company in the year 1883. You said that positively, and now to-day you say you are waiting proof of it. Now we have investigated this matter, and I put it to you, is it not a fact that Mr. Rankin Kennedy bought that dynamo, and worked it at the Woodside Works, the adjoining premises to you, to your knowledge?—I do not know that it is a fact.

WITNESS, continuing, stated that the voltage of the dynamo was 220 when it was double, and 110 when it was single. He never himself noticed the men put a bradawl or a bit of metal across the two wires. He did not believe the lamps went out when this was done. It would be a very foolish experiment to try. There was no difference in the size of the wires used. He was well acquainted at that time with that particular wiring, the three-wire system. What they had used at Siemens Brothers was *virtually* the three-wire system as they know it now.

When you say that you had used the thing over and over again at Siemens, was not the thing that you had used the use of a third wire as a common return?—We gave it that name, but we knew that it did not carry the whole of the current.

Were not the currents on the outside of like polarity?—They were not.

Witness then drew a diagram (J.D.A. 4) of what he said was used at Messrs. Siemens. The return wire was not larger than the others. The

Hosted by Google

middle ring in the larger Siemens' machine was of double size. After having bought the plant, he installed it at Messrs. Russell and Company's shipyard at Greenock.

Re-examined by Mr. FINLAY, witness stated that he had no idea of contesting the validity of Dr. Hopkinson's patent at the time of his interviews. He intended to uphold it if it could be upheld. With regard to the short circuiting tricks, he had since heard that the men used to play tricks while he was experimenting with his "plate" lamp in order to put it out, and he believed they succeeded in putting it out, and at the time he did not know why it went out. They also played a similar trick in order to put the other lights out. If by a tool being put across one branch the other lamps went up, it would show it was not the three-wire system. He was quite certain that this third wire was connected. He connected it himself. The third wire in certain cases at Messrs. Siemens was not confined to acting as a common return, but acted as a safeguard in the event of one arc lamp going out.

Mr. WILLIAM CLARK MUIR, examined by Mr. FINLAY, stated that he was one of the Directors of the National Electric Company in 1882. The user of the Siemens' dynamo and the installation were in no way secret. The installation was primarily for the purpose of assisting in the manufacture of an incandescent lamp. Other (Maxim) lamps were put up in the workshop for the purpose of lighting the shop.

Mr. GEORGE FORREST, examined by Mr. FINLAY, stated that he was an electrical instrument maker and was now in the employment of Messrs. Siemens. In 1882 he was foreman at the National Electrical Company's Works. He went to the Glasgow Works either at the end of January, 1882, or the beginning of February, and continued during the whole of 1882. He remembered the alternator referred to by Mr. Andrews being put up in the early days of March; he remembered distinctly three terminals on the machine. To the best of his belief the machine was connected with three wires, one to the outer circuit and a common terminal wire which went to the middle of the three terminals. The wires were led from the machine to the other end of the shop where there were two or more frames for the manufacture of incandescent lamps. There was also an arrangement at the corner where the flashing of lamps took place. In addition to that they had some leads laid off for lighting the shop when they were not using the current at the other end. They used a common return wire for both frames, having one frame on one side and some balance of lamps on the wall, and the other frame on the other side, or something of that kind. Previous to going early in May, 1882, to the Crystal Palace, he did not think he had ever seen Mr. Rankin Kennedy on business at the workshop. After his return from the Crystal Palace Exhibition early in June, Mr. Rankin Kennedy was at the workshop two or three times a week.

Cross-examined by Sir RICHARD WEBSTER, witness stated that all casual observers would see of the installation would be wires. He did not think Mr. Rankin Kennedy came to the workshop as early as April or May, 1882. Maxim lamps were used for lighting the shop. It might have been later than August that the Maxim lights were used. He knew of no putting of a connection across when the incandescent lamps were in question at all. He remembered the short circuiting of one side of the machine when Mr. Andrews was experimenting with his "plate" lamps. That would be confined to the period from March up to July.

Re-examined by Mr. FINLAY, witness stated after his return from the Crystal Palace Exhibition most of their time was occupied in perfecting the Kennedy lamp. Between March and July he did not think much use was made of the dynamo in connection with any installation of electric lighting.

Mr. JAMES McKELLOP, examined by Mr. FINLAY, stated that he was employed as tool maker and engineer at the Glasgow factory by the National Electric Company in 1882. He left at the end of November. He observed three wires, and that they went from the dynamo to the other end of the workshop. Between March and July, 1882, the dynamo was in use for lighting the workshop. The Maxim lamps were put up before he left for the Crystal Palace on May 5th. The alternator had three rings, three brushes, and three wires. He was not able to say from recollection how these wires were connected to the dynamo.

Cross-examined by Sir RICHARD WEBSTER, witness stated that he was an engine fitter, and had never had any electrical experience at all. As to voltage of the dynamo or of the Maxim lamps, he was perfectly ignorant of them.

Mr. CHARLES HUNTLEY TOWN, examined by Mr. FINLAY, said that he was now in the employment of Messrs. Mavor and Coulson, of Glasgow, as wireman. He had been in the employment of the National Electric Company from February to November, 1882, as instrument maker. He could not tell anything definite as to the connections; but three wires came from the dynamo, along the side of the shop, to the end of the shop. Maxim incandescent lamps were burnt, put up between March and May. He assisted in putting up the wires.

Cross-examined by Sir RICHARD WEBSTER, witness stated it was not the fact that up till the middle of 1882 whatever lighting there was by electric lighting was experimental.

A statement, signed by witness, and made by him to Mr. Owen ten days since, was then read over. It stated that, "Except some telephone work and dynamo brushes, the work at Sauchiehall-lane was of an experimental character. Nobody came about the place except those who had to do with the business. Although there were a few incandescent lamps about the place from time to time experimentally, the place was never lit for working by incandescent lamps. Gas was the real light we worked by." He had some recollection of three wires roughly fastened along the wall, but did not remember how far they went. On one occasion a man put a bradawl to the wires near the well-hole, and all the lights that were on went out. Mr. Andrews never had anything to do with the incandescent lamps.

Prof. SILVANUS THOMPSON, examined by Mr. WALLACE, stated that the alleged novelty of the patent was the bringing of the third wire back to the dynamo. The advantage of connecting the third wire with the dynamo was that, although they had the additional expense of copper in bringing that wire back to the dynamo, they could now turn out lamps one by one instead of two by two. Witness then read extracts from contemporary prints, showing the meaning attached in 1882 to the word "distribution." There was no special meaning of the word "distribution" known at that date. It had been suggested in the Court that "distribution" had a special technical meaning, and was confined to distribution in parallel; that was not the case. Witness then explained what he held to be the advantages of the Alexandra Palace "user." At the Paris Exhibition of 1881 the steadiest arc lamps of all were those of Mr. Gülcher, which were run at about 67 volts, all in parallel with one another. The suggestion that feeders were inapplicable to arc lights was absurd. They were in use every day for arc lights. Witness then gave his opinion as to the merits of the Inchicore arrangement. Between the diagram of Mr. Andrews relating to his workshop in Sauchiehall-lane, and the diagram of Dr. Hopkinson, there was no difference, saving that Dr. Hopkinson showed specifically two separate dynamos united in series, and the diagram that Mr. Andrews produced showed only one dynamo, presumably the one that he described with the two sets of coils. The Hopkinson system would not work with alternate currents without modifications. Witness then explained the mutual action of the two coils of regulator when alternate currents were used. It would not act efficiently without bringing to bear upon it subsequent knowledge.

Mr. JUSTICE ROMER: Really I ought not to take upon myself the examination of the witness, but I will ask him this question. [To the witness]. Will you look at the words, "A system of conductors for an electric supply at a fixed potential." Does that phrase show that, electrically, the system arrived at must be one where the parallel system alone is used?—No, certainly not. It included all cases whether of simple parallel or of parallels with series in them—all cases where the supply is a fixed number of volts.

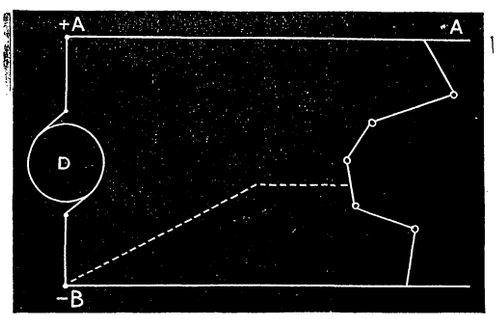
Speaking as an electrician, and only as an electrician, are there any electrical expressions here in this specification which, in your opinion as an electrician, point solely to a system of parallel lighting?—No, certainly not.

Cross-examined by Sir RICHARD WEBSTER at length upon diagram J.H. 1, witness said it was one way of arranging multiple parallel.

Sir RICHARD WEBSTER: Will you kindly draw me a system of conductors for supply at various points at a fixed potential which is *not* on the parallel system?

Mr. JUSTICE ROMER: That is exactly what I wanted.

The witness produced a diagram which was marked S.P.T. 3.



S.P.T. 3

Sir RICHARD WEBSTER: Now, you have there only got one bridge?—I have one bridge only.

And that is the only case which you can explain in which a distribution at many points—distribution of electrical supply—is to be at a fixed potential that is not parallel?—It is the only possible case.

The moment you put other bridges across you must have a fixed potential at all the points?—The moment you put other bridges across you have a system of parallel; they are in parallel one with the other.

In this S.P.T. 3 there will be both fixed current as well as fixed potential?—In that particular case, yes.

But let me point out to you you cannot make a number of bridges on the parallel system without having fixed potential.—They would not work well.

Kindly tell my Lord any passage in the specification or drawings which would lead a workman to apply the three-wire system to arc lights in series only.—In series only there is nothing whatever.

You have no doubt that Fig. 5 is an instance of multiple parallel bridge?—Certainly it is.

Now in fairness to this miserable patentee, to this ignorant man, will you kindly tell my Lord a single word that would lead the honest electrician to set to work to make arc lights in series and apply the three-wire system to that?—There is nothing to lead him to it, but there is nothing to prevent him doing what was done already, namely, using arc lamps instead of incandescent on his mains.

You have no doubt whatever that the indicator is only useful in the system of constant potential and varying current?—The regulator is distinctly for that purpose.

Does not that involve not only parallel bridge but multiple parallel bridge?—It involves the use of parallel bridges, but it does not say anything as to whether there shall be one, two, three, four, or five lamps in each bridge. It does not exclude that case.

The Court then adjourned until Wednesday.

Hosted by Google

WEDNESDAY, NOVEMBER 23RD.

On the hearing of the action being resumed, Prof. SILVANUS THOMPSON was recalled and further cross-examined by Sir RICHARD WEBSTER with reference to diagram S.P.T. 3. In the system as it was drawn one ordinary dynamo which produced sufficient voltage and sufficient current would do. It was only when they desired to burn two lamps separate from two others that any question of divided dynamo would come in or any question of another wire. Assuming that kind of dynamo to be used, the third wire would be useless. If a return were connected as shown by dotted line, it would break down the two lamps. If they had a constant voltage, and they cut out the extra lamps, the result would be that the remaining lamps, if glow lamps, would be broken down. With arc lamps the extra voltage might make them burn with longer arcs, but it would not break them down. Witness was next cross-examined with regard to diagrams illustrating his lecture delivered at the Crystal Palace in March, 1882. Witness admitted that in none of the diagrams did he, as a matter of fact, show a third wire taken back to a compound or double dynamo. A single dynamo of the proper kind would work perfectly well in any one of those systems.

Sir RICHARD WEBSTER: Can you point to any enunciation of the value of the three-wire system even in general, prior to Dr. Hopkinson's specification—in any text-book or printed book you can refer me to?—The nearest one I think I can refer you to is a description of dynamo with three terminals, with a middle terminal, suitable for this.

Where is that to be found?—At page 290 of Vol. I. of "Electric Illumination."

What time in 1882?—I think the date of the publication was August.

But that is not before Dr. Hopkinson's specification?—It was in August, 1882.

Have you ever actually tried the Inchicore or tried a system upon it with two bridges upon one side and three upon the other, or one upon the one side and two upon the other?—No.

Do you know that in order to get the lamps to burn equally you have to put in resistance to equalise the resistance on the two sides?—I should not have thought so.

What is there in this specification to lead people *not* to couple alternate dynamos rigidly?—There are no instructions as to coupling at all, and the practice was not to couple dynamos rigidly.

Do you suggest that a competent electrician dealing with this specification would not know that they must keep step?—I know of a case where they were coupled, simply each one to its own engine—no mechanical coupling between the two at all.

Cross-examination being continued, witness said he had never made an indicator according to Claim I. He would not undertake to say there was no case in which it could be made to work. He did not know of anyone on behalf of the defendants who had ever tried an indicator made according to Claim I. to see whether it would act or not. The passage on page 4, line 44, of the specification—"The application of this instrument to an extended system of electrical supply with a network of distributing mains is important. For each machine I prepare a pair of feeders of a size appropriate to the current they are to carry, but independent of the distance they have to go. Each pair of feeders goes to and is connected to some part or other of the system of distributing mains, and by the use of my invention I am able to keep the difference of potential constant at or near the point where the feeders join the distributing mains"—properly described a system of many bridges where the feeders took the current of constant potential to the place where the bridges were to be lit up. And it did *not* properly describe a system of one series where they had one main wire going out and another returning, and all the lamps in series on that.

Re-examined by Mr. FINLAY, witness stated that the use of the third wire had advantages in other cases than a system of parallel distribution. It had advantages in all cases of distribution save one, that was where the dynamos that were used—two together—were constant-current dynamos. In that case the middle wire could never have anything to do. He had looked at the part of the final specification which had been disclaimed relating to the use of meters and other things. As far as the meter was concerned, it would be applicable to all cases whether of parallel or series, or single working motors or arc lamps or incandescent lamps, saving only one case, that just referred to of constant current.

Mr. JAMES SWINBURNE, examined by Mr. FINLAY, stated that every arc lamp he knew of in 1882 would have worked in parallel. He found nothing in the specification confining it to a system of parallel distribution, only to a system of constant potential. The word "distribution" did not in 1882 refer particularly to distribution in parallel; it referred also to distribution in series. Taking the disclaimed portions of the specifications, they were in no way confined to parallel lighting. Witness then gave his opinion with regard to the advantages of the Alexandra Palace and Inchicore arrangements. Witness disagreed with Mr. Andrews' statement, that supposing the lamps at Glasgow on one side went up in brilliancy on short circuiting the other side, it would show that it was not the three-wire system. He thought it was quite possible that with an old machine of the type used then short circuiting one side might increase the electromotive force on the other. He differed from Mr. Andrews, because in the first place short circuiting one side of an old-fashioned machine took the load off that side, then the engine would go a little faster, and so the machine would give a little higher pressure on the other side. He had not tried it with a Siemens machine of this particular type, but he had used some time ago an old Gramme machine about the same date, and he found that even without going faster if they short-circuited one side the other side went up in electromotive force. A clever fellow might have thought of rigidly coupling up the two alternators, but certainly most people would not. In 1882 witness himself would not have been a sufficiently clever fellow to have thought of doing it. The regulator at Sardinia-street was not Dr. Hopkinson's regulator. At Sardinia-street they now used pilot wires. He had made a regulator according to the directions. He chose the way shown in Fig. 1. [Model handed to the witness.] It was made during the adjournment. He found that a regulator made as in Fig. 2 and connected up as in Fig. 1 could not be made to work, as far as he knew. The regulator was tested by Mr. Harrison, chief of the Standardising Institution in St. Martin's-lane.

Cross-examined by Mr. MOULTON, witness stated that in 1882 any electrician who knew that the alternators must keep in step had knowledge enough to know they must be rigidly coupled. With regard to his (J.S. 1) regulator, and the other one, there was no essential difference. As regards the position of the coils the exhibit S.P.T. 4 was most like Dr. Hopkinson's regulator. There the fine wire coils were end to end with the coarse wire coils, as shown in Fig. 2. The induction difficulty would not be appreciably increased by lapping the coarse wire coils round the fine wire coils.

Mr. MOULTON: Are you prepared to say that S.P.T. 4 will not work perfectly with alternating currents?—I should like to know how S.P.T. 4 is connected up. That is an essential part.

Connected up as in Fig. 1, or letting the whole current go through?—Letting the whole current go through I think it might work. I think it is very possible it would work. Putting a low-resistance shunt to it, as in Fig. 1, I think it certainly would *not* work.

Is it possible to have a system in which the mains are at constant potential where they are tapped by a customer without that being a parallel system?—It is possible in the case of its being only tapped once.

I never heard of *one* parallel line in my life! The only case in which it is not parallel is where the mains are tapped in only one place?—Yes.

In continuation of cross-examination, witness said: "Feeding conductors" was a known phrase, but oddly enough patentee did not use it in the usual way.

Cross-examined next in detail with regard to various passages in the specification, witness said that they pointed to parallel.

Mr. MOULTON: Is there anything in this specification which would direct a man to put up the system where you tap the mains only once?—No doubt, as I said before, Dr. Hopkinson was thinking of parallel. There is no direction about tapping at one place; but tapping at one place is a particular case of tapping at one or many.

With the exception of the Gülcher lamp, can you tell me one that was known to be able to work in parallel?—I do not know of any that were except the Gülcher; the question, as far as I know, never came up.

Re-examined by Mr. FINLAY, witness said that in connecting his regulator he endeavoured to follow the directions of the specification.

Mr. HUGH ERAT HARRISON, examined by Mr. FINLAY, stated that he had read the parts of Dr. Hopkinson's specification which specially referred to the regulator. He tested model regulator made by Mr. Swinburne with a direct current. It did not act very well, but it did act. He then tried it with an alternating current, and it failed. The regulator was connected in the manner described in the specification. He did not think it could possibly be made to work with alternate currents, except where the whole of the current passed through the thick wire coil.

Cross-examined by Sir RICHARD WEBSTER, witness said that prior to the case coming on he had not been consulted at all about the sufficiency of the regulators. The mutual induction was not much more likely to be set up when they had the thick wire bodily surrounding the thin and the powerful current running through the thick wire than it was when they had got the two windings end to end; the difference would be excessively small. Presuming that a gentleman in 1882 was minded to use alternating-current machines, he could not point to any direction in any book which would lead him to couple them otherwise than rigidly.

After re-examination by Mr. FINLAY witness withdrew.

Prof. ALEXANDER B. W. KENNEDY, examined by Mr. WALLACE with regard to the novelty of Dr. Hopkinson's patent, said that he agreed generally with the other witnesses that it consisted in bringing back the third wire to the dynamo. He found no limitation in the specification to the use of the system to incandescent lamps.

Mr. WILLIAM MORRIS MORDEY, examined by Mr. WALLACE, stated that he did not agree with Mr. Belfield that the three-wire system could *not* be worked on a single alternator. It could be worked with many advantages on a single alternator. In his opinion the three-wire system would be useful as applied to arc lighting. At that date (1881-82) arc lamps were used in parallel. The fact that was attracting most attention at that time was the successful working of arc lamps in parallel. That was the one fact that stood out in those two years as of most interest. He could give references to that from the technical press. With regard to the connection of the alternators at the date of the patent, on reading the specification, and being told that the arrangement shown in Fig. 5 was applicable to alternating currents, he could have worked the three-wire system on an alternating current machine,. It would not have been at all obvious in 1882 that he must put in rigid coupling. He was quite sure regulators, as shown in specification, would not work successfully with alternate currents.

Cross-examined by Mr. MOULTON, witness stated a regulator made on the lines of the specification might do for the backwoods, but it would not do for London. He was not content with a thing that was no use.

Dr. JOHN HOPKINSON was then re-called and further examined by Sir RICHARD WEBSTER, and stated that the model J.S. 1 was obviously different to the eye; it was different, and that difference was material. The arrangement of coils in the defendants' model was such as to increase the mutual induction between the two circuits. The mutual induction was the more important.

Cross-examined by Mr. WALLACE, witness said that there was nothing in his specification to lead a man to lay the thick coil over the thin. The only figure was Fig. 2, and that showed it as arranged in their own model.

Hosted by Google

Mr. RANKIN KENNEDY, examined by Sir RICHARD WEBSTER, stated that in October, 1881, he was residing at Paisley, near Glasgow, and was acquainted with Mr. Graham, an electrical engineer in Sauchiehall-street, Glasgow. He entered into an agreement with him for the sale of a patent. He first began to go to the Sauchiehall Works about the beginning of December, 1881. He saw Mr. Akester there, who was endeavouring to make incandescent lamps there. He knew a gentleman of the name of Forrest. He first knew him early in February, 1882. He knew Mr. Andrews. First met him about the end of January, 1882. On December 15th or 16th, 1881, he had a dispute with Mr. Graham, and for a time left him. It was made up again about the end of January or the beginning of February at Mr. Graham's house. About this time he was helping to light the Fine Art Gallery in Glasgow—that was early in November, 1881—on the simple multiple system, at first with Maxim lamps. The lamps had been obtained at the end of October, 1881. They were supposed to be 65 volts. He also knew Mr. Bottomley and Lord Kelvin. He had an intimate recollection of all that went on in the Sauchiehall-lane workshop, and the dynamo and the wiring and everything about it. It was a 2-H.P. Otto gas-engine. Shortly after the dynamo was fitted up, Mr. Andrews testing it. He tried to keep a current between the two outside terminals; the dynamo subsequently came into witness' possession, and was taken to pieces. All the coils were in series, with the broad ring cut out. With regard to the wiring at the works, his impression was that there were three wires put up from a dynamo that was down below the workshop, a Gramme machine. The number of the Siemens machine was 155 or 1,555. In March, 1882, when the Siemens machine first came, the workshop was lit up by gas. There was no permanent installation to light the shop with electricity. Never at any time. All done by gas. Sometimes a Maxim lamp was hung up temporarily, and light obtained from that. At no time did he ever see that middle wire go back to the dynamo. About May 19th or May 20th, 1882, on returning from the Crystal Palace, he altered the dynamo. He put it back into the same connection that it had when it came from Siemens'—with the broad ring as a common return. That was in June. At Woodside the dynamo was coupled up on a three-wire system; that was in 1884. Mr. Andrews was at Woodside, and came on to witness' premises. At no time, from anybody, neither from Andrews, Forrest, or Graham, did he ever hear either working on the three-wire system suggested or anything consistent with it. It was new to him when Dr. Muirhead told it to him at the end of 1882. After his return from London he saw some of the boys take a piece of wire and connect it across from the outer to the inner wire for the purpose of putting out some of the lamps. The effect was to put out the lamps on that side, and to brighten up those on the other. This could not have happened if it had been on the three-wire system. The lamps on one side of the Fine Art Gallery under certain circumstances used to get too bright and break down. They found when short circuiting took place on one side all the lamps went out on that side, and the others brightened up. That was on the compound parallel.

Cross-examined by Sir HORACE DAVEY, witness stated that he was in the employment of the National Electric Company during the spring of 1882, and had charge of the dynamo manufacturing at Polmadie, not at Sauchiehall-street. The main purpose for which he went to Sauchiehall-street was to experiment with his arc lamp. The manufacturing of his arc lamp had nothing whatever to do with the installation which Mr. Andrews speaks of. His impression was that the number on this Siemens dynamo was 155. The broad collecting ring was removed immediately the dynamo was first started. McKellop, a workman of Andrews, removed it. Witness was not present when he removed it. Connection was not replaced on March 28th; it may have been during his absence at the Crystal Palace.

Sir HORACE DAVEY: I will ask you distinctly. Are you prepared to state that Mr. Andrews' statement that the workshop was lighted with electric lights, and the current through the wires was used for the purpose of the manufacture of incandescent lamps, from March to June, is altogether untrue?—Part of it is because there was no lighting of the shop at any time.

Mr. Andrews was in charge of the shop, was not he?—He was.

You were a visitor?—Yes.

Will you undertake to say that Mr. Andrews' statement was untrue as to the lighting of the shop?—I will. There was no lighting of the shop.

No lighting of the shop at all?—There were some lamps fitted in the shop, but not on any system whatever.

The Court adjourned until Thursday.

THURSDAY, NOVEMBER 24TH.

On the further hearing of this case the cross-examination of Mr. Rankin Kennedy was continued, and further evidence was adduced on behalf of the plaintiff to rebut the defendants' evidence with reference to the alleged anticipation of the three-wire system by Mr. Andrews. Witnesses also on both sides gave evidence as to experiments made in their presence the evening before at the Westinghouse Company's laboratory with an apparatus constructed according to the first claim of Dr. Hopkinson's patent, in order to demonstrate whether or not the apparatus would work with alternating currents. Lord Kelvin and Dr. Bottomley, as well as Dr. Hopkinson, alleged that the experiments proved that the apparatus could be effectively worked, while Mr. Swinburne's evidence on behalf of the defendants was to the effect that the result of the experiments did not show that the apparatus could be used commercially. Sir Horace Davey commenced to sum up the defendants' case, and argued that the plaintiff's specification for the three-wire system was wide enough to cover the use of a third wire, as applied at Inchicore and at the Alexandra Palace. He had not completed his argument at the rising of the Court. A full report of the proceedings will appear in our next issue.

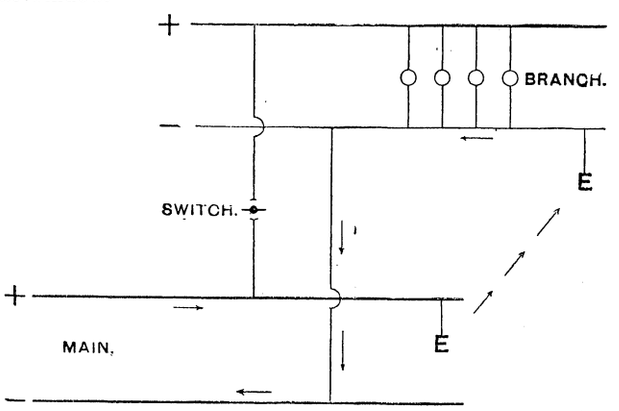
CORRESPONDENCE.

THE REGENT STREET FIRE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It would appear from a paragraph in your last week's issue, anent the recent fire in Regent-street, that you have satisfied yourself the cause of that fire was in nowise connected with the electric installation. As the circumstances are somewhat peculiar and interesting, and as I have reason for doubting the correctness of your conclusions, I shall be glad if you will permit me to lay before you a few facts concerning the fire worthy of consideration.

The fire was first discovered about four o'clock in the morning in an enclosed bay window, and in the vicinity of a plastered iron column, to which was attached a vertical row of incandescent lamps and their reflectors, the whole being draped with plush. A second column was similarly lighted and draped, and above was a horizontal row of lights capable of being raised and lowered, with flexible attachments. The window had not been entered for several days (nearly a fortnight) and there was nothing whatever in the nature of the goods displayed that will for a moment sustain the supposition of spontaneous ignition. In fact, there was nothing in that window capable of generating heat beyond the lighting arrangements—which, in this case, were wholly electric. The lamps were on three separate minor circuits controlled by single pole switches. It appears these lamps had all been switched off on their respective circuits about eight o'clock in the evening, that is to say, fully eight hours before the outbreak of the fire. Current, however, was otherwise on throughout the night in the shop. Now, under these circumstances there are but two possible hypotheses as to the cause of the fire, and both have to do with the lighting of that window.



First, there is the possible contact of the drapery with one or more of the lights, leading to charring, smouldering, and eventually flame. The second is that of an "earth" on one of the circuits. I regard the first as too improbable to be sustained, but, as regards the second, I find no such difficulty.

"What!" it will be asked, "an *earth* after the current had been switched off eight hours?" Well, at first sight, the objection appears fatal to the theory, but upon closer inspection the obstacle disappears.

Without troubling you with too many details, let me say there is ample evidence in connection with the wiring to account for an "earth," provided there was current in the branch. In considering this question of current it is important to remember the lamps were switched off on one pole only, and by aid of the accompanying diagram it will be seen, with certain conditions granted, how it was possible for an earth to have been maintained after switching off.

Assume in the first place an "earth" on the main *positive* pole—an assumption fully warranted in this particular case. Next assume also an earth on the opposite pole of the window circuit, and upon which there was no switch, again requiring no great stretch of the imagination. You have thus the chain completed. The diagram shows at a glance how it was possible for a leak to have been maintained throughout the night after

Hosted by Google

switching off. With this granted there is ample evidence to account for the appearance of the fire on or about that window column.

Now, Sir, this opens up the important question of "earthing." It is well known, though perhaps not admitted, that upon many supply companies' mains there exists considerable leakage on one pole or the other, and a few years' experience seems to point to the impossibility of practically maintaining both poles rigidly above the potential of the earth on large public supply systems. If that be so, then I say advisedly it is time to reconsider our position. Our rules are framed and our wiring based largely upon the supposition of "no earth." If "no earth" is a fallacy then equally so are our rules, and the present system of wiring needs overhauling. Instead of having, as we fondly believe, two strings to our bow, we have but one, and that often a very weak one. But with a known and constant weak side in our mains (obtainable only by earthing one pole) we should know better how to meet and provide for contingencies of the kind referred to. For instance, had the side of the house installation shown earthed in the diagram, been connected to the known earthed main, and the side in which the switch is inserted connected with the insulated main, then it will be seen no such mishap as I have surmised could have occurred.

Earthing is simplicity itself with concentric cables and fittings, but there are difficulties to be overcome in connection with existing installations on other systems. I do not despair, however, in their being eventually surmounted, provided all interested co-operate in bringing about a much-needed change.

I am well aware that what I have here written will be regarded by many of my *confrères* and others as little short of rank heresy, but I invite them to carefully consider the matter, when they will find there is more in it than appears on the surface.

With apologies for the length of this letter.—Yours, &c.,

Guardian Fire Office, H. HUMAN.
11, Lombard-street, E.C.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The city authorities invite tenders for the electric lighting of Santiago, Chili, and will receive same until March 1, 1893.

SALES BY AUCTION.—The sale by auction of the contents of the East Down Electrical Works, East Down Park, Lewisham (lately in the occupation of Messrs. A. B. Gill and Co.), a preliminary announcement of which appeared in our last issue, has, it will be seen by our advertisement columns, been fixed for Tuesday, the 13th prox.

——— Messrs. Wheatley Kirk, Price, and Goulty are issuing the complete catalogue of the valuable boilers, engines, machinery, machine tools, stores, &c., of the Springfield Works, Basford, and the Queen's-road Works, Nottingham, which will be sold by auction on the works premises on Tuesday and Wednesday next, the 29th and 30th inst., commencing at 10 for 11 each day. A large quantity of bleaching, dyeing, dressing and finishing machinery is included in the sale, all of which is in excellent condition. The Queen's-road works are within five minutes' walk of the Midland and Great Northern Stations at Nottingham, and the Basford Works are within 15 minutes train journey of Nottingham.

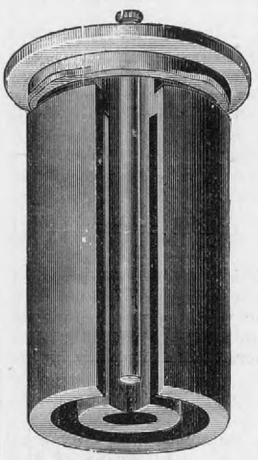
DISSOLUTION OF PARTNERSHIP.—Messrs. Hubert Fielden Jackson and William Leopold Whittaker, carrying on business as electrical engineers at 85, Queen Victoria-street, E.C., under the style of W. L. Whittaker and Co., have dissolved partnership. Accounts will be received and paid by Mr. H. F. Jackson.

MESSRS. BUMSTED AND CHANDLER. — Messrs. Bumsted and Chandler have just put in two 60-H.P. engines at the Naval and Military Club, Piccadilly, in conjunction with Messrs. Crompton and Co., who have supplied the dynamo and apparatus for the installation. The output of each Crompton dynamo is 110 volts, 400 amperes, 425 revolutions; they are of the single-limbed type, with iron magnets. The armatures are of the drum-wound type, the conductors being bars of Crompton patent compressed stranded cable on the outside of the core, and strip copper bent to correct shape at the ends of the core. The engines have each two high-pressure 8in. cylinders and two low-pressure 11in. cylinders, with piston valves at the sides, cutting off steam in the high-pressure cylinders at half stroke, boiler pressure=140lb., at which pressure the engines indicate 72 H.P., the exhaust being turned into the brick chimney stack. The engines are said to be singularly free from vibration and noise.

MESSRS. J. G. STATTER AND CO.—We have to acknowledge the receipt of the new catalogue and price list issued by this firm, which is replete with information respecting the Statter dynamos and motors, engines, and engine accessories, foundation work, electric traction, fittings, instruments, lamps, &c., and the general appearance of the book is creditable to all concerned. Messrs. Statter and Co. have joined the long list of electrical firms who have come to the conclusion that it is best and wisest to devote considerable care and attention to their price lists, and they will, doubtless, be fully recompensed for the additional outlay incurred. The only complaint we have to make is that the firm's name on the cover is illegible. Such price lists as these are indispensable to architects, contractors, and other large indenters and users of electrical plant and apparatus, and will be carefully preserved.

TELEPHONE AMALGAMATION.—The *Glasgow Herald* of Wednesday last contained a gossipy leaderette on a scheme for amalgamation between the National Telephone Company, the New Telephone Company, and the Consolidated Telephone Construction and Maintenance Company, which is sufficiently inaccurate in some particulars to justify us in assuming it to be chiefly gossip. We have been unable to obtain any confirmation from head-quarters.

MILL LIGHTING.—Messrs. W. H. Allen and Co. have recently completed an installation of the electric light in the York-road Mill for the York-street Spinning Company of Belfast. The installation consists of 65 32-c.p. and 20 16-c.p. incandescent lamps, with the necessary generating plant and accessories. The switchboard and connections have been so arranged as to permit of easy extension. A special insulation has been adopted for the cables and fittings to adapt them to withstand the effects of the hot and damp atmosphere of the spinning-room.



THE STANDARD BATTERY.—Messrs. Shippey Bros. send us a specimen of a cell, known in America as the Law battery, but which in this country will be known as the "Standard." It consists of an ordinary zinc rod and two split cylinders of carbon or agglomerate, arranged as in the illustration. An ebonite cover grips the top of the jar with wedge bayonets. In the absence of tests we can say nothing of the performance of this battery. The idea of arranging the zinc in this way seems to be that a larger surface of carbon can be utilised. The only real test of the utility of this plan would be a careful observation of the internal resistance, and this we have had no opportunity of making. We note that in the American advertisements of this battery it is stated that "the element is everlasting, and is so guaranteed."

ELECTRIC HEATING.—We have received from Syracuse N.Y., a descriptive pamphlet, giving illustrations of various kinds of electric heaters, including car heaters, office heaters, grating, or mat heaters, kettle heaters, cooking stoves, &c.

MESSRS. DRAKE AND GORHAM.—This firm have secured the contracts for lighting the residences of Baron H. de Worms, M.P., in Grosvenor-place, W.; Sir E. H. Carbutt, in Hyde Park-gardens; and Mr. Wood, in Lowndes-square; and also of the business premises in Moorgate-street for Messrs. Schwann Bros. Sir Gervas Glyn at Ewell, Mr. Hallett at Orpington, and Mr. Herman at Cambridge, have placed orders with the firm.

BAZAAR LIGHTING.—A successful bazaar was held last week at the Vestry Hall, Turnham Green, S.W. The walls were tastefully illuminated by incandescent lamps, the current being derived from accumulators. The whole of the electrical gear was kindly lent by Mr. R. A. Scott, of Acton Hill, and the installation was carried out by members of the Acton Hill Engineering Works, who gave their services. Owing to a ball having been held on the premises the previous evening, the electrical work had to be carried out during the night. The Countess of Winchelsea and Nottingham, who performed the opening ceremony, expressed much pleasure at the effective illumination of the hall.

Hosted by Google

COLLIER AUDIBLE TELEPHONE SYNDICATE (LIMITED).—Creditors of this Syndicate (in voluntary liquidation) must send particulars of their claims to the liquidator, Mr. Godefroi Drew Ingall, 4, Coleman-street, E.C., on or before December 16th.

SIAM.—The Brush Electrical Engineering Company (Limited) have received advices by cable from their representatives at Bangkok that the central station plant supplied by them to the Siam Electric Light Company (a reference to which Company appeared in our last issue) has undergone the fortnight's trial prescribed by the arbitrators under their award with complete success, and to the entire satisfaction of the experts, and that the balance of moneys due thereon has been paid over by the Treasury.

THE LONDON CHAMBER OF ARBITRATION, GUILDHALL.—This Chamber, which has been established by the Corporation of the City of London, with the co-operation of the London Chamber of Commerce, for the speedy and inexpensive settlement of disputes arising in the course of business, has now been organised, and it is to be hoped that the facilities thus provided for disputants will enable them to settle their differences without having recourse to expensive litigation, and especially such trade disputes as can best be dealt with by experienced men of business.

MR. THOMAS PARKER.—Mr. T. Parker, of the Electric Construction Corporation (Limited), Wolverhampton, was the recipient last week of a handsome brougham and an illuminated address from the Liberal electors of the Kingswinsford division of Staffordshire. It will be remembered that Mr. Parker unsuccessfully contested the division in the Liberal interest at the last election, and made a plucky fight.

ELECTRIC LIGHT AND ATHLETICS.—Mr. Lang, the proprietor of the Carrick-street Cycling and Athletic Grounds at Ayr, has recently introduced the electric light, the result being a distinct success. At the recent trial, the effect gave so much satisfaction to those present that it was resolved to postpone several important athletic events, in order that they might take place at night instead of in the daytime, the result being that a very much larger number of people witnessed the sports than would have otherwise been the case to the profit of the management. There is room for development in this direction.

COUNTRY HOUSE LIGHTING.—Benmore, near Kilman, Argyleshire, has recently been fitted throughout with the electric light. A Priestman patent oil engine supplies the motive power, the installation consisting of about 180 lights. The electroliers and fittings used in the installation were specially designed by Munro's Electrical Manufacturing Company (Limited), and the installation was carried out under the supervision and to the specifications of Mr. W. A. Bryson, of Glasgow. Messrs. Ernest Scott and Mountain (Limited) supplied the electrical machinery, and contracted for the erection of the plant.

DUNDEE.—Mr. C. Martin delivered an interesting lecture before the Dundee Mechanical Society last week on electric light and power. Lord Provost Matthewson presided, and the room in the Technical Institute, where the lecture was delivered, was crowded. After the lecture a cordial vote of thanks was accorded to Mr. Martin.——At the last monthly meeting of the Gas Commission it was agreed to fix the electric meter rents on a scale of 12½ per cent. on the cost of the meters, the meters selected to be used being Ferranti, Aron, or Kelvin. In reply to a question as to the progress which is being made with the works, it was stated that they were proceeding very rapidly, and that doubtless the city would be lighted by electricity about Christmas. Twenty-five per cent. of the total capacity of the present works had already been completed.

EALING.—At the Local Board meeting last week it was decided to expend the sum of £50 in procuring the report of an expert as to the advisability of inviting schemes for lighting the district by electricity. The Electric Lighting Committee of the Local Board had visited some of the districts which have already adopted the electric light, and recommended the course above referred to.

GUILDFORD.—The Electric Lighting Committee of the Urban Sanitary Authority has not yet met to discuss the subject of adopting the electric light for the district; but the members have collected a mass of evidence, which will shortly be laid before the local authority.

NORTHAMPTON.—The Lighting Committee of the Town Council have decided to extend the electric light, which was recently adopted for the large fountain in the Market Square, to the lighting of the whole square.

TORQUAY.—At their meeting last week the Torquay Town Council, after electing the Electricity Committee, discussed the question of the Electric Lighting Order, which expires in July next. Mr. Hex, who brought the matter forward, understood that it would not be necessary to take steps for the promotion of a Provisional Order as the Board of Trade had notified him that these Provisional Orders did not as a rule lapse simply because the compulsory works were not completed within the time limited by the Order. The discussion which followed showed that the members were taking a keen interest in the subject of the lighting of the town.

EXETER.—At the meeting of the Exeter City Council last week a letter was read from the Board of Trade calling attention to a complaint made by the Exeter Electric Lighting Company, that power had been granted to private persons to open up the streets for the purpose of supplying their own private premises with the electric light, and complaining that this power had been granted without the local authority insisting upon conditions similar to those contained in the Provisional Order granted to the Company. The Company asked the Board of Trade to exercise the powers vested in them by the Electric Lighting Acts, and to notify the local authority that they have no power to authorise breaking up the public streets for the purpose of laying electric mains by any persons other than those possessing a Board of Trade Licence or Provisional Order. After some discussion, it was decided to write to the Board of Trade simply acknowledging the receipt of the letter.

ISLINGTON AND HACKNEY.—The Vestry of the former and the Board of Works of the latter Authority have given notice of their intention to apply for a Provisional Order to enable them to produce a supply of electricity for public and private lighting. It is proposed to open up the principal streets in the district, including High-street and Upper-street, Islington; Holloway-road and Seven Sisters-road; High-street, Kingsland; High-street, Stoke Newington; Kingsland-road, Mare-street, Stoke Newington-road, and Dalston-lane.

LIVERPOOL.—The Mayor of Liverpool, Mr. R. D. Holt, has offered to instal the electric light in the large ball room of the Town Hall, but the Finance Committee of the Corporation think the work should be undertaken at the public cost, and the matter has been referred for consideration.

ELECTRIC TRACTION.—Before the Liverpool Polytechnic Society on Monday last a Paper on Electric Traction was read by Mr. F. G. Baily, of Universty College, Liverpool. After an historical account of the application of electricity as a tractive force, Mr. Baily described the methods now in use in the various traction systems.

LECTURES ON ELECTRICITY.—A series of free lectures is being given at the Picton Lecture Hall at Liverpool, and on Tuesday last Dr. Howard, of University College, explained to a crowded audience the various applications of electricity.

LLANDUDNO.—At the last meeting of the Improvement Commissioners the question of a considerable extension to the Gas Works came under consideration. The Chairman of the Lighting Committee informed a member that the question of electric lighting had not been overlooked.

RHONDDA VALLEY.—The localities of Cwmdare and Cwmparc in the Upper Rhondda, where the collieries of the Ocean Colliery Company are situate, and where the Company have hundreds of workmen's cottages, have recently been lighted by electricity, the generating plant being situate in the fan engine-house and the motive power produced by the fan engine. The light has also been extended to the chapels in the district.

JUNIOR ENGINEERING SOCIETY.—On Saturday last a party of members of this Society were shown over the Richmond Lock, Weir, and Foot Bridge Works by Mr. C. Le Neve Foster and Mr. E. Duncan Stoney, representing the Thames Conservancy and the contractors for the works, Messrs. Ransomes and Rapier.

SYDNEY, N.S.W.—The electric light is making steady and important progress in Sydney, and amongst the recent installations is that at the large wool stores of Messrs. Dalgety and Co., Miller Point, Sydney, where the electric light has been fitted throughout the large buildings (including the whole of the large wharves owned and occupied by Messrs. Dalgety) by the Electrical Material and Lighting Company (Limited). The lamps used for the wharf lighting are portable, and are found to be very convenient, as they can be moved from place to place wherever necessary for the work. One Brockie-Pell arc lamp of 2,000 c.p. is included in the installation. The dynamos are of the Manchester type.

WEST OF ENGLAND LIGHTING.—An article appears in the *Western Morning News* of the 16th inst. commenting upon the slow progress of the electric light in the West of England. The article is carefully written, and should have the effect of awakening an interest in the subject of municipal lighting in the west. The writer points out the many advantages of electric lighting over gas, and deals with the subject from a statistical point of view, showing how general the installation of the electric light is becoming, and calling upon the local authorities of Devon and Cornwall to bestir themselves in the matter.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

October 25, 1892.

19,184. O. IMRAY. London. An improvement in incandescent electric lamps. (The Westinghouse Electric and Manufacturing Company, United States.)

19,194. C. L. DAVIES. London. Improvements in telephones and in the application thereof to railway signalling.

October 26, 1892.

19,220. E. FREUND. London. Improvements in electric batteries. (E. Freund, Austria.)

19,222. D. SALOMONS and L. PYKE. London. An improved apparatus for the production of electric currents, alternating in direction with great frequency.

19,236. G. WILKINSON. Lancashire. Improvements in and relating to the generation and distribution of electrical energy.

19,242. A. OBLASSER and C. THÉRYC. London. Improvements in cases for containing electric batteries and the like. [Date applied for under Patents Act, 1883, Sec. 103, April 26, 1892, being date of application in France.]

19,248. C. E. WEBBER. London. Improvements in conduits for electrical conductors.

October 27, 1892.

19,282. W. WALKER. Birmingham. An improvement in or connected with galvanic batteries.

19,293. R. BAUMANN. London. Improvements in electric lock and alarm.

October 28, 1892.

19,361. A. S. FORD. London. An improved process of electro-plating glass, china, &c.

19,385. W. LOWRIE. London. Improvements in or relating to the distribution of electrical energy and in maintaining the potential thereof.

19,386. W. LOWRIE. London. Improvements in or relating to the supply of electrical energy for propelling or lighting purposes upon electrical railways.

19,387. SIEMENS BROTHERS AND CO., LIMITED. London. Method of increasing the speed of signalling in submarine or subterranean cables, and the construction of such cables for this purpose. (Messrs. Siemens and Halske, Germany.)

19,393. T. FROGGATT. London. Improvements in electric battery apparatus.

19,404. J. S. RAWORTH. London. Improvements in or relating to safety cut-outs for electric generators, transformers, and motor generators coupled in parallel.

October 29, 1892.

19,451. H. F. JOEL. London. Improvements in voltaic batteries, electrodes, and connections.

19,478. A. PALAZ and V. DUBOUX. London. Improvements in electrical apparatus for increasing the adhesion of the wheels of engines on railway rails.

October 31, 1892.

19,496. W. LOWRIE. London. Improvements in and relating to electro-magnets and magnetic circuits.

19,497. H. CLEGG. West Norwood. Improvements in electric lamps and in their manufacture.

19,543. L. B. STEVENS. London. Improvements in electric indicating apparatus.

19,547. R. DAMSEAUX. London. Improvements in microphones.

19,569. O. FERGUSSON. London. Improvements in electrical connections.

November 1, 1892.

19,602. A. B. BLACKBURN. Manchester. Improvements in electric switches.

19,646. W. LOWRIE. London. Improvements in the method of supplying electrical energy of required potential to electric current circuits.

19,655. H. G. O'NEILL. London. Improvements in and relating to a method of and means for heating by electricity.

19,657. R. EWING. London. Improvements in underground conduits for electric cables.

19,665. G. S. HOOKER. London. Improvements in and relating to telephonic apparatus.

19,671. M. W. POLLARD. London. Improvements in means for conducting electricity for electric lighting and other purposes.

November 2, 1892.

19,690. O. A. ENHOLM. Manchester. Improvements in and connected with the distribution of current in incandescence electric light circuits. [Date applied for under Patents Act, 1883, Sec. 103, October 3, 1892, being date of application in United States.]

19,699. D. SINCLAIR. Glasgow. Improvements in telephonic apparatus.

19,714. H. CHITTY. London. Improvements in dynamo electric machines.

19,729. C. POLLAK. London. Improvements in and means or apparatus for rectifying alternating currents for working continuous current motors, and for electrolytical purposes.

19,730. G. J. PHILPOTT and A. J. WILLETT. Brighton. Improvements in distributing boxes for electric light, and power mains for underground and aërial purposes.

19,738. THE EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED, and E. A. GIMINGHAM. London. Improvements in portable electric safety lamps and batteries and appliances for charging them.

19,739. E. L. JOSEPH. London. An improved electrical switch.

19,749. H. HARRIS. London. Improvements in the construction of indicating and transmitting instruments for telephones.

19,758. W. LOWRIE. London. Improvements in electric conductors.

19,761. H. R. MALTBY. London. Improved means for obtaining electricity on board ship.

November 3, 1892.

19,771. J. MUIRHEAD. Glasgow. Improvements in and relating to telephonic instruments.

COMPANIES' MEETINGS & REPORTS.

Swan United Electric Light Company (Limited).

The tenth annual report of the Directors of this Company for the year ending September 30th last is issued, and will be presented to the shareholders at the ordinary general meeting to be held at the Cannon-street Hotel, E.C., on Tuesday, the 29th inst., at 12 o'clock.

The profit and loss account for the year shows a credit balance of £34,840. 11s. 11d., which, together with £8,010. 3s. 10d. brought forward from the last account, makes disposable the sum of £42,850. 15s. 9d. An interim dividend in respect to the first half of the year amounting to £14,558. 9s. 8d. has already been paid. The Board proposes that a further sum of £21,467. 8s. 4d. be divided free of income-tax, and that £6,824. 17s. 9d. be carried forward. The distribution of this amount in accordance with Clause 77 of the Articles of Association will work out at 4s. 2⅜d. per share on the 78,949 ordinary shares of the Company, £3. 10s. paid, and at 4s. 11⅜d. per share on the 19,750 £5 fully paid, being equivalent to 10 per cent. per annum on the partly paid, and of slightly under that rate upon the fully paid, shares. The dividend will be paid upon the register as it stood upon the 15th November inst., and the warrants will be issued on December 13th.

Hosted by Google

The litigation on the German patents of the Company having happily terminated, and the bulk of the capital of the Company being now invested in the Edison and Swan Companies in Great Britain and France, the Board believe that the time has arrived when a fusion of the residuum of the foreign business of the Swan Company with the British Edison and Swan Company may be effected with advantage to both interests, and negotiations are pending with a view to effecting some arrangement in this direction.

The Directors desire to record their sense of the loss which the Company have sustained by the death of Mr. F. R. Leyland, Deputy-Chairman of the Company. The Directors have elected Major Samuel Flood Page, who had been Secretary and Manager of the Company for several years, to a seat on the Board. The Directors who retire by rotation are Mr. J. S. Forbes and Mr. E. W. Batt, who, being eligible, will offer themselves for re-election. Messrs. Welton, Jones and Co., the auditors, will also retire, and will offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

COMPAGNIE DES FORCES ELECTRIQUES.—A Company with the above title has been formed in Paris, the chief promoters of the undertaking being M. Richemond, the Compagnie de Construction Electromécanique, the Compagnie Continentale Edison, the Société Générale des Téléphones, and Messrs. Ménier.

HEATLEY AND GRESHAM (LIMITED).—This Company was registered on November 15th, with a capital of £10,000, in £50 shares, to manufacture machinery, motors, boilers, &c., of all descriptions, and to carry on the business of mechanical and electrical engineers, iron workers, iron and brass founders, &c.

SCARBOROUGH ELECTRIC SUPPLY COMPANY (LIMITED).—This Company was registered on November 17th, with a capital of £50,000, in £10 shares. The objects are to carry on the business of electrical engineers and contractors, suppliers of electricity, undertakers for the supply of electricity for lighting, transmission of power, and other purposes, whether public or private, and manufacturers of, and dealers in, all apparatus and things required for, or capable of being used in connection with, the generation, accumulation, supply, distribution, and employment of electricity; to promote, support, and obtain any Acts, Provisional Orders, licenses, and other authorities necessary or desirable for carrying out any of the objects of the Company, and in particular to take a transfer of the powers, duties, and liabilities granted to, or imposed upon, the Mayor, Aldermen, and Burgesses of Scarborough by the Scarborough Electric Lighting Order, 1891. The subscribers are :—

	Shares.
Richard F. Steble, J.P., Ramsdale Bank, Belmont-road, Scarboro'.	50
George Alderson-Smith, J.P., Wheatcroft Cliff, Scarborough	50
John Dale, J.P., Netherbank, Scarborough.....	50
John W. Woodall, St. Nicholas House, Scarborough.....	50
George L. Beeforth, J.P., Belvedere, Scarborough.....	50
Hon. Charles A. Parsons, Heaton Works, Newcastle-upon-Tyne	50
John B. Simpson, Hedgefield House, Blaydon-on-Tyne	50
A. A. Campbell Swinton, 66, Victoria-street, Westminster, S.W.	50

WRIGHT AND BUTLER LAMP MANUFACTURING COMPANY (LIMITED).—This Company was registered on November 17th, with a capital of £100,000, divided into 4,000 Preference and 6,000 ordinary shares of £10 each, to acquire, take over as a going concern, and carry on the business of lamp manufacturers, brass and ironfounders, tin-plate workers, chandelier manufacturers, glass merchants, &c.

MISCELLANEOUS.——ANTI-FRICTION ROLLER BEARING SYNDICATE (LIMITED), capital £30,000, in £1 shares.——JAMES SAMPLE AND CO. (LIMITED), mechanical engineers, &c., capital £2,000, in £10 shares.——LEACH AND CO. (LIMITED), engineers, capital £5,000, in £5 shares.

ABELL'S ELECTRICAL ENGINEERING COMPANY (LIMITED).—The statutory return of this Company, made up to September 8, 1892, has been filed. The Company was registered on May 3, 1892, with a capital of £5,000, in £5 shares. At the time of making-up, 360 shares were taken up, of which 120 were issued as fully paid to the vendors. Upon the remaining 240 shares £3 per share has been called, resulting in the payment of £650, leaving £70 in arrears.

R. C. CUTTING, DOUGLASS, AND CO. (LIMITED).—At extraordinary general meetings of the members of this Company, held at the office on September 20th and October 7th, special resolutions were passed and confirmed that the Company be voluntarily wound up, and that Mr. S. J. Skelton, of Wardrobe-chambers, E.C., be the liquidator.

ELECTRIC TRUST (LIMITED).—The annual return of this Company made up to October 10th, was filed on October 19th. The Company was registered on June 24, 1889, with a capital of £60,000, in £10 shares, and in December, 1890, the capital was increased to £60,200 by the creation of 200 founders' shares of £1 each. At the time of making-up, 1,675 £10 shares and 167 founders' shares were taken up, the full amounts called, and all calls (£16,917) paid.

SHEFFIELD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The statutory return of this Company, made up to September 12th, was filed on November 15th. The capital of the Company is £98,000, in 14,000 shares of £7 each. At the time of making up 3,999 shares had been taken up, all of which had been issued with £5 considered as paid on each share. These shares have been issued to those shareholders in the Sheffield Telephone Exchange and Electric Light Company (Limited) who agreed to take partly-paid shares in the new Company in full consideration for their interest in the old Company.

TAYLOR AND TUCKER ART METAL COMPANY (LIMITED).—The annual return of this Company, made up to August 20th, has recently been filed. The Company was registered on May 10, 1889, with a capital of £5,000, in £1 shares. At the time of making-up, 4,400 shares were taken up, the full amounts called, and all calls (£4,400) paid.

COMPANIES TO BE STRUCK OFF THE REGISTER.—Tuesday's *London Gazette* contains a notification that at the expiration of three months the names of a great many companies will be struck off the register and the companies will be dissolved, unless cause is shown to the contrary. Amongst them are :—

Cooper's Patent Glass-lined Metal Piping Company (Limited)—taken over by Dan Rylands (Limited).
H. D. Cooper and Co. (Limited).
Durand Electric, Petroleum, and Gas Engine and Manufacturing Company (Limited).
Johannesburg Electricity Supply Company (Limited).
Morgan's Automatic Electric Signal System Syndicate (Limited).
Universal Electric Light and Power Trust Corporation (Limited).

CITY NOTES, &c.

CALLS DUE.—*Dec. 15th:* NATIONAL TELEPHONE COMPANY (LIMITED), £1 on 90,950 Five per Cent. Non-Cumulative Third Preference £5 shares.—*Dec. 30th:* ISLINGTON AND GENERAL ELECTRIC SUPPLY (LIMITED), final £1 on 45,000 £5 shares.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended November 20 were £899, as against £792 for the corresponding period of last year, being an increase of £107. The total receipts for half-year amount to £17,007, against £15,357 in the corresponding period of 1891, being an increase of £1,640.

DAN RYLANDS (LIMITED).—The Directors' report shows that the Company has experienced a prosperous year. After meeting interest charges and providing for the redemption of debentures, the Directors are able to recommend that a dividend of 10 per cent. be paid on the ordinary shares and that £733 be carried forward to the new account. Nearly £3,000 has been taken from revenue during the year to maintain the machinery and plant in good working order, and since the establishment of the Company in 1888 debentures to the extent of £14,800 have been redeemed out of profits.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—Mr. George Herring has been elected Chairman of the Company in succession to the late Duke of Marlborough. The Directors have declared an interim dividend at the rate of 20 per cent. per annum for the six months ending the 30th inst. on the ordinary shares, payable on and after December 15th next; and the transfer books and register of members will be closed from December 1st to 15th (inclusive), for the purpose of preparing the necessary warrants.

HOVE ELECTRIC LIGHTING COMPANY (LIMITED).—As announced in our last issue, the statutory meeting of the shareholders of this Company was held on Monday last at the offices, Mansion House-buildings, E.C., with Colonel Felgate, R.E., in the chair. The report and accounts of the Directors were adopted, and the Chairman announced that 1,300 8-c.p. lamps had already been applied for, and that negotiations were in progress for the lighting of the Town Hall and the streets of Hove. On the motion of Mr. Albright, seconded by Mr. Sutton, a vote of thanks to the Chairman for presiding brought the meeting to a close.

MESSRS. RICHARD HORNSBY AND SONS (LIMITED).—The Directors of this Company recommend the payment of a dividend of 6 per cent. on the Preference Stock for the past half-year, and 2s. 6d. per share on the ordinary shares, making, with an interim dividend, 5s. per share for the year, free of income-tax. The dividend will be paid on and after the 15th proximo.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—This Company give notice that the coupons of the Company's issue of £50,000 Five per Cent. Registered Debentures, due on December 1st next, will be paid on and after that date by the bankers, Messrs. Prescott, Dimsdale, Cave, Tugwell, and Co. (Limited), of 50, Cornhill, London, E.C., or at the Royal Bank of Scotland, 123, Bishopsgate-street Within. The register for debenture holders will be closed till December 1st.

SCARBOROUGH ELECTRIC SUPPLY COMPANY (LIMITED).—A prospectus is issued inviting applications for 2,000 shares of £10 each in this Company, payable £2 on application, £2 on allotment, and the balance by instalments of £2 at not less than monthly intervals. The authorised capital of the Company is £50,000. The Directorate includes the Hon.

Hosted by Google

C. A. Parsons and Mr. A. A. Campbell Swinton (Managing Director and Consulting Engineer). The secretary is Mr. John Hall, 102, Westborough, Scarborough. The prospectus states that the Company is formed for supplying electricity for lighting, power, and other purposes in the town of Scarborough. The Company has taken over a Provisional Order obtained by the Corporation in 1891, and they will pay the Corporation the sum of 500gs. to cover the expenses incurred in obtaining the Order. Applications for shares should be in not later than December 3rd next.

SPANISH NATIONAL SUBMARINE TELEGRAPH COMPANY (LIMITED).—The numbers are announced of 89 bonds, amounting to £8,900, of the Six per Cent. Mortgage Debentures drawn for payment at par on or after December 31st.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts for the two weeks ended November 15th show a decrease of £185, as compared with the corresponding period. The July receipts, estimated at £4,114, realised £4,129.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Nov. 18, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,965.

TELEGRAMS: "INDICES," LONDON.

WHEATLEY KIRK, PRICE and GOULTY

(ESTABLISHED 1850).

ELECTRICAL AUCTIONEERS, VALUERS, AND ARBITRATORS.

49, QUEEN VICTORIA STREET, LONDON, E.C.

And Albert Square. MANCHESTER.

SALES BY AUCTION, &c.

Re A. B. Gill and Co.

SALE of ENGINEERING and ELECTRICAL FIXED and LOOSE PLANT, MACHINERY, DYNAMOS, MOTORS, ELECTRICAL FITTINGS, GAS ENGINES, PATTERNS, and other effects.

WHEATLEY KIRK, PRICE AND GOULTY are instructed by the Trustee, Arthur Clarke, Esq., TO SELL BY PUBLIC AUCTION, on TUESDAY, the 13th December, 1892, commencing at 10 for 11 o'Clock prompt, the ENTIRE CONTENTS of the EAST DOWN ELECTRICAL WORKS, Dermondy-road, East Down Park, Lewisham, S.E.

Comprising:—8-H.P. Vertical Engine and Boiler, by Davey Paxman and Co.; 6 and 14-H.P. Otto, 2-H.P. Stockport, and 2-H.P. Clark's Gas Engines; Six ¾-H.P. Electrical Motors, Brush, Victoria, Elwell-Parker, E.P.S., Siemens, Gramme, Gills, and Plating Dynamos; 4½in. Stroke Shaping, Horizontal Milling, Planing, Drilling, and other Machines; Fly Presses, Shafting; Six Hand Lathes, 4, 5, and 6in. Centres; 6½in. and 8½in. Slide Surfacing and Screw-cutting Lathes; 46 E.P.S. 23L Accumulator Cells in glass boxes; Switches, ½-H.P. Motors, Valuable Marble Standards, Electroliers, Brackets in brass and hammered-iron Canvas Belting, Loose Tools, Utensils, and other effects.

May be viewed on Monday, December 12th, 1892, and Morning of Sale.

For descriptive Catalogues and any further particulars apply to ARTHUR CLARKE, ESQ., Trustee, 6, Lombard-court, E.C., or to WHEATLEY KIRK, PRICE and GOULTY, Electrical and Mechanical Auctioneers, 49, Queen Victoria-street, London, E.C.; And Albert-square, Manchester.

Telegrams: "INDICES," London.

BELFAST HARBOUR.

The BELFAST HARBOUR COMMISSIONERS are prepared to receive TENDERS for the LIGHTING of QUEEN'S QUAY, ABERCORN BASIN, and the HAMILTON GRAVING DOCK by ELECTRICITY.

Specification and Form of Tender, and any further information, may be obtained from Mr. George Combe, Electrical Engineer, 3, High-street, Belfast.

Sealed Tenders, addressed to the undersigned, and endorsed "Tender for Electric Lighting," to be sent in on or before the 12th proximo.

The Commissioners do not bind themselves to accept the lowest or any Tender.

W. A. CURRIE, Secretary.

Harbour Office, Belfast, 25th November, 1892.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).

NOTICE is Hereby Given that the TRANSFER BOOKS of this Company will be CLOSED from THURSDAY, December 15, to TUESDAY, December 20, both days inclusive, preparatory to paying an Interim Dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income tax, for the quarter ended September 30 last, and payable on December 21.

By order, RICHARD COLLETT, Secretary.

Winchester House, Old Broad-street, London, E.C., November 30, 1892.

MESSRS. DEBENHAM, TEWSON, FARMER, and BRIDGEWATER have a large selection of SHOWROOMS, OFFICES, WAREHOUSES, and FACTORIES suitable for ELECTRICAL ENGINEERS.

Their Monthly List is now ready, and may be obtained at their Offices, 80, CHEAPSIDE, E.C., or will be forwarded free by post

CHEAP PREPAID ADVERTISEMEN *relating to* **SITUATIONS VACANT AND WANTED, PLANT WANTED, FOR SALE, AND FOR EXCHANGE, &c** *are inserted in "The Electrician," at the following low rates:*

Three Lines and Under ... ... **1s. 6d.**

Per Line After ... ... **6d.**

Nine Words to the Line.

SITUATIONS VACANT AND WANTED, &c.

ARMATURE WINDER.—WANTED one used to Gramme and Drum Bar Armatures.—Apply to the MANAGER, Newton Electrical Engineering Works, Taunton.

ELECTRICIAN WANTED to test Dynamos, Transformers, &c.—Apply to the MANAGER, Newton Electrical Engineering Works, Taunton.

WINDERS WANTED, accustomed to Drum Armatures.—Apply, giving reference and wages required, CROMPTON AND CO. (Limited), Electrical Engineers, Chelmsford.

ELECTRICAL ENGINEER (21), 4 years' workshop experience, 3 years' abroad; used to Triple Expansion Engines; Constant Current Dynamos; wiring and testing, wants ENGAGEMENT at home or abroad.—"F. M.," 83, De Beauvoir-road, Kingsland, N.

YOUNG MAN (21) as IMPROVER wants Job, shop and out door.—Address, "J. M. W. T.," 48, Broomhouse-road, Fulham, S.W.

PARTNER WANTED by an old-established firm of Merchants, who, having made advantageous arrangements with large Continental Works, are about to add an electric light, &c., department to their business.—Address, "N. T.," care Davies and Co., Advertising Agents, Finch-lane, Cornhill.

Miscellaneous Advertisements, Plant Wanted and for Sale, &c., &c., continued on next page.

WORKING PARTNER WANTED in an old-established, though not extensive electrical engineering business, with £300 to £400 at disposal, to buy out two others (sleeping), and assist advertiser in extending business. Works and offices well fitted, and very conveniently situated; good regular trade.—"X. Y.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

WANTED ESTIMATES for SUPPLYING an ELECTRIC LIGHT PLANT, with 20-light dynamo, and 20 lights fixed with all requisites to a factory 50 miles from London. Tenders to "Electric," care of Deacon's Advertising Offices, 154, Leadenhall-street, E.C.

OLD ESTABLISHED ENGINEERING BUSINESS in YORKSHIRE FOR DISPOSAL under special circumstances. Works and Plant capable of employing 150 hands easily. Bears a high reputation for its products, chiefly heavy engineering tools for British and Foreign Governments, and most of the principal engineering firms. Although a current going concern, an exceptionally low price will be taken. Freehold Land, Buildings, Plant, and Contents under £10,000 for an immediate purchaser.—Apply to WHEATLEY KIRK, PRICE, and GOULTY, 49, Queen Victoria-street, London, E.C.

WANTED to PURCHASE, several second-hand BRAIDING MACHINES for light work.—THE UNITED ELECTRIC WIRE CO., 14A, Clerkenwell Green.

WANTED TESTING SET for Laboratory work, measure up to 5 Megohms, Mirror, Galvanometer, &c., complete.—Apply, "P. G.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

FOR SALE.—Over 100 ORNAMENTAL IRON STANDARDS, suitable for overhead wiring or street lamp-posts.—Apply EXETER ELECTRIC LIGHT CO. (Limited).

SALE OF PATENT.—The English Patent of an electrical apparatus, affording safety against thieves, burglars, &c., is TO BE SOLD.—Inquire W. RICHTER, Avondale, Batheaston, Bath.

Messrs. WILLIAMS and NORGATE, Importers of Foreign Books, have weekly parcels from the Continent with all the new Scientific Books.

(*Foreign Prices*).

14, HENRIETTA STREET, COVENT GARDEN, LONDON, & 20, S. FREDERICK STREET, EDINBURGH.

"THE PATENTEES' HANDBOOK,"

BY

J. G. LORRAIN, M.Inst.E.E., M.Inst.M.E.,

CHARTERED PATENT AGENT,

Gives full information and advice to intending Patentees. Sent post free on application to Mr. J. G. LORRAIN, Norfolk House, Norfolk-street, Strand, London, W.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 759.—Vol. XXX FRIDAY, DECEMBER 2, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The French counterpart of the Electrical Trade Section of the London Chamber of Commerce, the Syndicat Professionnel des Industries Électriques, seems to be strikingly similar to our own institution. As at Botolph House, the attendance is usually small, and the discussions long and luminous. Thus, at the last meeting of the Syndicat Professionnel the first subject discussed was the question of arbitration; should or should not the Syndicat undertake such duties? The President, M. Sciama, was inclined to say no, since the Tribunal de Commerce was not legally bound to accept the decisions nor the litigants to submit to the jurisdiction of the Syndicat. In the end, however, the duties of arbitrator were undertaken, these admittedly cogent objections notwithstanding.

The next business of the meeting was the nomination of a technical assessor for the Tribunal de Commerce, a function, alas! which the Electrical Trade Section is not likely as yet to be called upon to perform. Next followed a report with regard to the interviews which had taken place between M. Sciama and M. Méline, President de la Commission des Douanes, in regard to the proposed Franco-Swiss tariff. This tariff-mongering, again, is not a piece of work which is likely to fall to the lot of those who attend the meetings at Botolph House.

The last item on the programme was a big one, like its title, being nothing less than a *projet de création d'un bureau de contrôle des installations électriques à l'interieur des habitations.* M. Fontaine set forth the difficulties which he had encountered, even in the preliminary stages, in realising this project; there were so many people to please—electricity supply companies, wiring contractors, consumers. It was generally agreed that the establishment of a central, impartial, and competent body to supervise interior wiring, draw up rules, and grant certificates was desirable, and likely to meet with considerable support, "provided the contribution demanded was not too onerous." A final decision, however, was deferred until the Syndicat should meet again "enlightened by the discussion which had just taken place."

Manganin has received a bad character, though professors have praised it; the alloy has been under a cloud, although the highest authority in the land has publicly extolled it; at least two of our most careful instrument makers tried it and found that not only did it fail to fulfil its early promises, but that it behaved in a curiously capricious manner. Whether the first imported samples were of an inferior quality or whether the full instructions for use were not given, or if given, were neglected—which we think is the least likely explanation—has not transpired. But we are glad to be able to report that manganin is recovering its lost reputation; and at least one engineer, if he swears at all, on which point we have no definite information, swears by it. To announce the discovery of an alloy, the electrical resistance of which is practically independent of its temperature, is a matter of very considerable importance, but to give great credit to the scientific institution which was responsible for the announcement was rather premature.

An interesting account by Dr. Lindeck of the properties of manganin will be found elsewhere in our present issue, and it is there recorded that Mr. Weston, of Newark, U.S.A., observed the low temperature coefficient of manganese alloys. When Lord Kelvin stated at Edinburgh during the discussion at the British Association that the Physikalische Anstalt had not been in existence two years before this valuable alloy was discovered, Prof. von Helmholtz interposed the remark that the discovery had been made by an American engineer. This, because Mr. Weston was domiciled in America. Prof. S. P. Thompson, however, observed that Mr. Weston was an Englishman. Graham Bell, Tesla, and a score of others whose nationalities have not yet become fused into that strange ethnical alloy, the American nation, commonly pass as Americans, and their discoveries are credited to that Republic.

The assertion made some years ago that manganin had a negligible temperature coefficient was sufficient to induce instrument makers to experiment with it, but when they found it to be unreliable, no repetition of such assertions would induce them to spend time in investigating its peculiarities. The important process of annealing at 140°C. for five hours is clearly insisted upon by Dr. Lindeck, but he gives no information about the effect of insulating materials upon it. The best paraffin is being abandoned for resistance coils, since even this sometimes attacks the wires; but paraffin seems to have a very marked effect on manganin, and it suffers not only from oxidation but in mechanical

Hosted by Google

manipulation, unless carefully annealed. With the exception of some imported resistance boxes, "made in Germany," we have heard of its use in considerable quantities only from Mr. CROMPTON, who has constructed some very large water-cooled resistances, which, in connection with his improved potentiometer, serve to measure with great accuracy the large currents generated by supply stations.

THE minor conveniences of electric lighting add up eventually to no small sum, though this cannot be expressed in absolute dimensions; suffice it that these amenities outweigh the apparently cheaper cost of gas. The imposition of any inconvenience, even if it be only the use of short-lived lamps, should be discouraged, and anything that would entail the sudden extinction of all the lamps in a house on account, not of an accident, but of an error of judgment on the part of the consumer, should by all means be avoided. And yet we understand that it has been seriously proposed to enforce that which may be called the "Leeds" system of charging, by adjusting of the main fuse. By this system, our readers will remember, each customer is to be called upon to declare "the maximum number of lights required to be in use at any one time," and a system of rebates is based on this declaration. We have already remarked that only a very few customers are likely to benefit even by the first step of this sliding scale.

IN the "Hopkinson" or "Manchester" method of charging the maximum current must be declared, but Prof. KENNEDY points out in our Correspondence Columns this week that the notion of using the main fuse is obviously out of the question, and he proposes a current indicator with a non-return pointer. This is an improvement upon our suggestion of a recording instrument, but the question of what really is the maximum current, is raised. There is in most houses what may be called a normal or family maximum, and on occasions, which are numerous or rare in proportion to the hospitality of the household, there is a festive or maximum maximum, and even this may be exceeded on exceptional occasions. The difficulty arises in deciding which of these is to be the maximum for the purpose of settling the charge. To take the normal maximum will be to check the use of portable, occasional, or temporary lamps, and, indeed, to encourage householders of moderate means to leave some of their reception rooms unwired. To take the festive maximum will be to render the rebate practically inoperative. We are not altogether favourably inclined to Dr. HOPKINSON'S plan and look upon it rather as an ingenious method of making both ends meet in an otherwise unprofitable district.

WHILE the "Leeds" and the "Hopkinson" methods of charging have been contrived from the point of view of the supply company, M. HOSPITALIER has some advice to offer to consumers. The lamp curves, which will be found in another column, are interesting, but we agree with M. HOSPITALIER that it will be very difficult to get the general public to understand the argument, even if the exact *smashing point* could be clearly indicated.

WALL-SOCKETS with switches are among the many minor blessings of domestic electric lighting. The ease with which the current may thus be turned on compared with the fumbling with a plug commends itself to all who use them. But a little accident which has happened at Sir DAVID SALOMON'S laboratory suggests that there may be something more than convenience in such an arrangement, and in sending us the result he writes that he has always insisted upon the combination of a switch with a wall-socket on the score of safety. The plug in question was used with a Kelvin multicellular voltmeter. One of the contacts is in good condition, but the other is burned, and has been unmistakeably fused, as though a six or eight ampere arc had played for a few seconds. Sir DAVID SALOMONS assures us, however, that the damage was done bit by bit over a period of about six months. Occasionally the voltmeter did not move, and the plug was "pushed a little"—and at last it failed. The cover and base being fireproof, no harm was done. Sir DAVID SALOMONS has been good enough to give us further information on this subject in reply to our inquiries, and he points out that a No. 18 S.W.G. copper wire was not destroyed, and therefore a sudden short circuit must have been out of the question. Mr. PREECE'S experiments on fuse wires, however, show that no less than one hundred amperes are required to fuse No. 18 copper wire, though, of course, it would carry much less when covered in. We still hesitate to accept the "bit by bit" theory, but little accidents like these are worthy of careful attention, and we have been indebted to Sir DAVID SALOMONS on former occasions for interesting details of such failures.

O.S.A.—A full report of Mr. Ll. B. Atkinson's presidential address on "Human Dynamics" will appear in our next issue, revised by Mr. Atkinson.

Electric Light Mains in Paris.—It is said that at least two of the Paris electricity supply companies propose to relay their entire network of mains.

Electric Traction in Sweden.—The Municipality of Stockholm has granted a concession to the Stockholm-Rimbo Railway Company for an electric tramway.

The South Staffordshire Cars.—Mr. Dickenson, general manager to the South Staffordshire Tramway Company, made arrangements to inaugurate the electric system yesterday.

Post Office Appointment.—Mr. J. Gavey, superintending engineer, to be principal technical officer in succession to Mr. Hookey, who has been appointed assistant engineer-in-chief.

Belfast.—In consequence of a decision arrived at by the Belfast Harbour Commissioners, a considerable portion of the County Down side of the harbour will, at an early date, be lit by electricity.

Cable to the Andamans.—The question of connecting Port Blair with the main land by cable has, says the *Indian Engineer*, been once more shelved by the Government of India on the ground of financial exigencies.

The Chicago Auditorium.—The auditorium building at Chicago is lighted by electricity by means of an isolated plant which is the largest of the kind. The installation comprises 25,000 incandescent and 200 arc lamps.

Sir John Pender.—The Queen held an investiture of the Order of St. Michael and St. George at Windsor Castle on Tuesday last, at which Sir John Pender was formally invested with the insignia of the Order.

Electrical Courses.—The Turçoing Chamber of Commerce has recently inaugurated a course of instruction in industrial electricity adapted for workmen and foremen, and has confided the work of instruction to—M. l'Abbé Courquin.

Hosted by Google

Cambridge.—The Electric Lighting Company turned on current for the first time last week. It is stated that the Master of Magdalen has applied for an injunction to compel the Company to abate the nuisance caused by their generating station.

The Joy Valve Gear.—Mr. David Joy, the inventor of the well-known valve gear, is applying for an extension of his patents for "improvements in steam engines." Caveats from those opposing the extension must be filed before December 20th next.

Hamburg.—The streets of Hamburg are to be electrically lighted, and the principal roads are now furnished with arc lamp standards. The method used in Milan, of suspending the lamp in the middle of the street by means of a cross wire, is also being tried.

Yarmouth.—The Electric Light Committee (consisting of the whole Town Council), sitting to discuss and determine the question of the introduction of the light into the town, have resolved to recommend the Council to undertake the lighting of the borough by electricity, involving an outlay of £20,000.

Hove.—The electric lighting of Hove was formally inaugurated on Monday evening at the Town Hall in the presence of a large and influential gathering, presided over by Mr. Woodruff, J.P., Chairman of the Hove Commissioners. The formal switching on of the current was performed by Lady Louise Loder.

Discoveries of Metals.—According to *Industries* a further discovery of plumbago has been made at Baddegama, in the Galle district, Ceylon, the vein being 4ft. thick, and lying close to the surface. A new discovery of platinum and iridium has also recently been made in the Mudgee district of New South Wales.

Montreal.—A petition, said to have about 10,000 signatures, has been sent to the City Council against the running of electric cars all the winter. The plea for this is that the streets on which the cars run will be almost bare of snow and prevent sleighing, while other streets will be covered with snow and forbid wheeling.

Exhibitions.—After some difficulties, which have now been satisfactorily surmounted, the project for holding in Rome in 1895-96 an International Exhibition of Fine Arts and Electricity is said to be under way. This is intended to solemnise the twenty-fifth anniversary of the annexation of Rome to the Kingdom of Italy.

Wandsworth.—The Wandsworth District Electric Supply Order, 1890, has been revoked by the Board of Trade, the promoters having failed to comply with requirements. An Order has been applied for by the County of London Electric Lighting Company for the supply of electricity throughout the whole of the district of the Board.

Toynbee Hall Electrical Society.—Mr. R. W. Paul, of 44, Hatton-garden, has kindly presented the members of this society with one of his latest pattern Ayrton-Mather reflecting galvanometers (d'Arsonval type) for use in the laboratory at 34, Commercial-street. Competition among other electrical firms in this direction would be appreciated.

Physical Society.—Owing to pressure on our space we have been compelled to hold over our report of the proceedings at the last meeting of this Society. Without diagrams Messrs. Rimington and E. Wythe Smith's Paper on "Experiments in Electric and Magnetic Fields, Constant and Varying" would be unintelligible, and the diagrams occupy a considerable amount of space.

The Atlantic Cables.—A report appeared this week that an amalgamation between the Commercial Cable Company and the French Cable Company had been effected by the purchase of the control of the French Company by the Commercial Company. There is no truth in these rumours, nor is it likely that such an amalgamation can be effected, seeing that French law directs that French cables must be owned by French citizens.

Simla.—The question of lighting Simla with electric light is under consideration, and it is proposed, if a practicable scheme is prepared, to form a company to carry it out. Engineers are examining the project for drawing the requisite power from the Sutlej. On account of the expense, however, this project, says the *Indian Engineer*, is likely to be given up in favour of another, which would draw the power from the municipal waterworks.

Transmission of Power in Cassel.—The Cassel transmission of power plant was described by Mr. Kapp in a Paper read by him at the recent meeting of the British Association in Edinburgh. (See *The Electrician*, Vol. XXIX., p. 422.) This installation possesses several remarkable features, not the least being that it has paid, although only in operation nine months, the profits, it is stated, being about 25 per cent. of the receipts, which were about £3,500.

Electric Power Transmission in Scandinavia.—The largest electric transmission of power plant in Sweden has recently been installed at Grycksbo, in the Kopparberg district. At a distance of about two and a-half miles from the paper mills is a waterfall, whose power has now been utilised for the working of the mills; a turbine of 60 H.P. being fixed at the waterfall. The current is transmitted along a copper wire, 6·4 millimetres in diameter, suspended by means of oil insulators.

The Marseilles Electric Tramway.—According to *La Lumière Electrique* the electric cars at Marseilles are not meeting with an unqualified success. It has been found necessary to put in new and more powerful motors, which is not surprising if, as our contemporary alleges, 40-passenger cars have often to take 70 passengers up an incline. The Administration also have found it necessary to double all the telephone circuits contiguous to the line at the expense of the tramway company.

"Wire to Wire" Electric Communication.—In a letter to *The Times* of Wednesday, Col. J. R. Magrath, late assistant to the Director-General of Telegraphs in India, begs to say that, before the Mutiny in 1857, Sir William O'Shaughnessy, Director-General of Electric Telegraphs in India, made fairly successful experiments in the direction of "wire to wire" communication, which no doubt would have been continued and improved but for the Mutiny needing their utmost efforts to keep the telegraph lines in workng order.

Electric Lighting in North Kensington.—The Works Committee of the Kensington Vestry having recommended that an application be made to the Board of Trade, and all other necessary steps taken to obtain the revocation of that portion of the House-to-House Electric Light Supply Order, 1889, relating to North Kensington area, and that it be referred back to the Works and Sanitary Committee to consider what action should be taken with a view to obtaining a supply of electrical energy in the area in question, the recommendation was adopted at the last meeting of the Vestry.

Hull.—Following the example of the St. Pancras Vestry, the Town Council of Hull has determined to give the local electric light installation contractors, most of whom are agents for the large electrical firms, the opportunity of exhibiting electrical appliances. The Exhibition will be held in the Sessions Court, and it will probably be open to the public for five days. The object is to give the public the opportunity of gaining information and witnessing the advantages of electricity. Messrs. Crompton have arranged to give an exhibition of cooking by electricity. The municipal central station will be completed by Christmas.

Photographing Vowel Sounds.—At the recent International Congress of Physiology at Liège, Prof. Hermann, says the *Engineer*, showed the possibility of photographing the relative vibrations produced by the vowel sounds. The vowels were sung into a phonograph. Immediately afterwards they were reproduced very slowly, and the vibrations recorded by a microphone. The latter was furnished with a mirror which reflected the light of an electric lamp upon a registering cylinder, covered with sensitised paper and protected by another cylinder with a small opening which gave passage to the rays of light from the reflector. By this means was obtained very distinct photographic traces, and the constancy was remarkable for the different letters.

Electricity Supply in Paris.—The electricity supply business seems to be turning the corner even in Paris, where it labours under several unnecessary disadvantages. The report of the Société anonyme d'Éclairage Électrique du Secteur de la Place Clichy, which serves a district somewhat similar in character to

Hosted by Google

that allotted to the Metropolitan Electric Light Company, although considerably smaller, made a net profit during the year which ended on June 30th last of over £7,000, the gross receipts amounting to £26,000. On June 30, 1891, 9,517 lamps were connected to this Company's mains; on June 30, 1892, the total was 29,522. The main mileage is 20½, and the cable mileage 121½. It is proposed to increase the Company's capital by £40,000, making a total of £160,000.

The Electric Light and Plant Life.—At the meeting of the Manchester Association of Engineers on Saturday last the discussion on Mr. B. H. Thwaite's Paper on "The Economic Possibilities of the Generation of Electromotive Force at the Coalfields, and its Distribution and Application to Industrial Centres" was concluded. After the discussion an interesting demonstration of the effects of the actinic rays emitted from the electric arc on organic plant life was given by Mr. Thwaite. The growth of plants, he said, could be appreciably accelerated by the judicious use of the electric light. The leaves of the *acacia cophanta*, closed in sleep, and removed from darkness into the beam of the arc, opened almost immediately, the leaves nearest the root being the first to be influenced.

Société Générale des Téléphones.—The experts nominated to adjudicate in the dispute between this Company and the State as to the value of the material summarily taken over by the latter from the former on September 1, 1889, have decided that 9,300,000frs. would be an equitable sum to pay for it. To this 1,100,000frs. interest should be added. The Société Générale has already received 5,000,000frs. on account. The net outlay of the Société Générale was 14,336,000frs., so that, at this rate, it will sustain a loss of over 4,000,000frs. The Société Générale also claims to be compensated for the value of the plant as forming part of a going concern. Although their opinion was only asked with regard to the value of the material, the experts have, it is said, reported that they think the additional claim should be allowed. According to *L'Industrie Electrique*, it has been proposed to form a special company to fight the State in the Law Courts.

The Thomson-Houston Lightning Guard.—In an article which we reprinted last week (p. 95) from *L'Electricien*, testimony was borne to the great practical value of the well-known Thomson-Houston electro-magnetic lightning guard. In a recent issue *L'Industrie Electrique* prints an abstract from a letter addressed by the manager of the St. Brieuc central station (see *The Electrician*, Vol. XXVI., p. 757) to the Thomson-Houston Company in Paris of similar import. The extract reads as follows:—

"During the evening of October 13th-14th an extremely violent storm burst over the town and neighbourhood. The lightning struck the primary line running from the Ponts Neufs Station to the distribution network three times, giving rise on each occasion to a discharge spark about 1 metre long. These discharges were carried away to earth before traversing the dynamo, and the lightning protector immediately broke the short circuit formed by the arc and restored the line current. The extinction was instantaneous and the restoration of the circuit almost immediate. For an hour small discharges occurred in one or the other of the two lightning arresters, discharges evidently due to a small electrostatic charge which had accumulated on the primary wire. In the station there is a lighting line which comes from a transformer and conveys the current for the lighting of the station and workmen's shed a little distance off. This line was also struck, and *not* being protected by a lightning guard, it was ruptured and the transformer burnt out."

The Admiralty and Departmental Inventors.—A revised regulation has been issued by the Admiralty on the subject of patents for inventions. It states that any officer or subordinate employed in a civil capacity in an administrative, a manufacturing, or an experimental department under the Admiralty is to understand that he accepts such employment subject to the condition that if he is desirous of taking out a patent for any invention he shall, before seeking provisional protection, obtain their Lordships' approval, the application being made through the head of his department and accompanied by a full description of his invention. Permission to patent will not be granted as a matter of course, but each application will be dealt with according to the circumstances of the case. Where the invention is or may be applicable to the use of Her Majesty's service their Lordships' approval, if granted, will be subject to such conditions as to assignment of the patent or to its use by the Government as they may think fit to impose. In defining such conditions, and in the settlement of terms for the use of the invention, regard will be had to any facilities in originating, working out, and perfecting the invention which the inventor may have enjoyed by reason of his official position.

County Council Lecture on Electricity as applied to Mining.—The Technical Education Committees of the County Councils of Nottingham and Derbyshire have arranged for the delivery of a third series of lectures for the benefit and instruction of mining engineers and colliery managers. These lectures are being given by Prof. Robinson, Prof. Clowes, and George Fletcher, Esq. In connection with the series, Prof. Robinson on Saturday, the 26th ult., in the University College, Nottingham, gave a very practical dissertation upon Electricity as applied to Mining. The lecturer had arranged, by the courtesy of various firms, an interesting series of experiments illustrative of the generation and transmission of electricity. A large number of diagrams showing the coupling of various types of machines, and the application of motors to pumping, hauling, winding, and coal-cutting, gave a practical illustration of the text of his lecture. Messrs. J. Davis and Son, of Derby showed one of their patent safety motors, and Mr. Albion T. Snell lent some valuable drawings illustrative of electric locomotives suitable for mining work, and also a series of drawings showing developments in electric coal-cutting machines, with which he has been largely identified during the past few years. Messrs. Crompton and Messrs. Goolden and Co. also lent interesting diagrams and apparatus.

The Westinghouse Incandescent Lamp.—Great interest, says *Industries*, has naturally been shown in the new Westinghouse incandescent lamp, which is to be outside the Edison patent. The lamp, so far as it has been described up to the present time, is disappointing. We do not in the least sympathise with Edison, as we do not consider he invented the lamp, but given that the judges, after going into the matter carefully, think he did, he is legally entitled to the monopoly. The attempts to evade his patent seem puerile so far. The claim is for a globe made entirely of glass. Surely this cannot be circumvented by using a separate glass stopper. Clearly a glass bottle with a glass stopper is made entirely of glass, and luting the stopper would not put it outside the description. The doctrine of "mechanical equivalents" would, of course, cover this in England; but, we believe, the American practice is to follow the literal meaning of the words of the claim more closely. We wonder some one does not hold that the ordinary lamp is outside the claim because the platinum wires themselves act as a minute portion of the globe, so that the globe is not entirely of glass. Another scheme is to employ silicate of soda for sealing in the wires. How this helps the matter it is difficult to see. Silicate of soda is one kind of glass, and is commonly known as "water glass." The property of dissolving in water does not make it no longer a glass. The insolubility of calcium or lead glass is a mere accidental property, with no direct bearing on the matter, and using a soluble glass can hardly be seriously taken as avoiding Edison's patent, even if it admits of leading-in wires not made of platinum, as obviously any other wire might be used if it could be sealed in properly. If some one now found out that he could make lamp bulbs of, say, a mixture of cryolite and fluorspar, and that the material would seal in copper wires, the use of this material would still be a detailed modification of Edison, and could not in fairness be taken as being outside his patent, whether the law says so or not.

THE WYNNE SYSTEM OF ELECTRIC TRACTION.

In *The Electrician* of February 28, 1890 (Vol. XXIV.), a report by Messrs. Mordey, J. Raworth, and Scott Russell upon the Wynne tramway system was published, and gave rise to a lively correspondence. The various patents for a sectional contact rail, whether a mid-rail or tram-rail, and the methods of putting a number of sections into contact with a buried conductor were discussed, and the claims of other inventors were set forth. In Mr. Wynne's system a contact rail is laid in the middle of the track, flush or nearly flush with the roadway, and is crenellated so as to fit between the granite sets; this zigzagging of the rail ensures that the short sections of

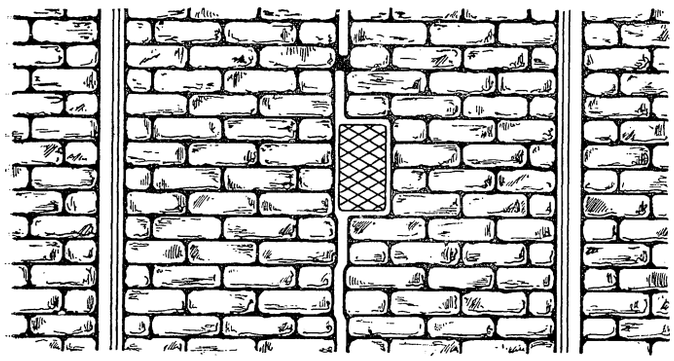

FIG. 1.—Part of Track showing Tram Lines, Mid-Rail,and Contact Box.

which it is composed will not alter their relative positions, and offers some foothold for horses. The leading feature of this system is that only those sections actually covered by the moving car are charged, that is, connected with the buried conductor. The sections are 5ft. long, and five of them, at least, are always covered by the car; they are laid on asphalte concrete, and are run in with bitumen, which affords tolerable insulation between the sections and from the earth. These sections are charged in pairs as the car moves over them.

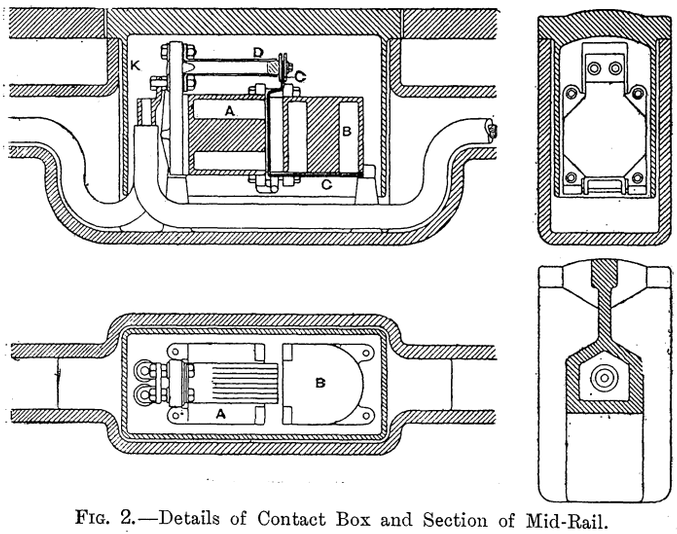

FIG. 2.—Details of Contact Box and Section of Mid-Rail.

Mr. Wynne has recently modified the details of his system, and by placing the contact boxes between two sections, he is able to reduce the number of magnetic switches while retaining the important principle that only those sections which are under the car and its platforms are charged. The contact boxes are placed at intervals of 10ft. The covers of these boxes are constructed on the diving-bell principle, the enclosed air preventing water from rising into the interior. The connections are easily accessible, and the contacts may be quickly replaced. A part of the line in Fig. 1 shows a contact box with portions of the crenellated rails.

Before proceeding further, the details of the contact boxes must be described. In Fig. 2 two sections and a plan of this device are shown, together with a section of the mid-rail, showing the buried conductor. This conductor is led into the box and the two ends are brought up and sweated to a double shoe from which the current is tapped off. This shoe is a single casting, and consists of two thimbles or ferrules united by a cross piece. The ends of the conductor sections are turned up and enter these ferrules, one of which is shown in the side elevation of the contact box. A pair of split contact springs are provided, and the shoe is connected to the lower one. Two tubular magnets A and B are mounted in the box, and to save space, they are arranged one vertically and the other horizontally. The windings and connections of these magnets are not shown in our illustration, but they are easily described. Two insulated wires are connected to the upper contact spring. One of these goes to one magnet and thence to the cast-iron case of the box, thus putting it in connection with one section of contact rail. The second wire goes to the other magnet, and thence runs alongside

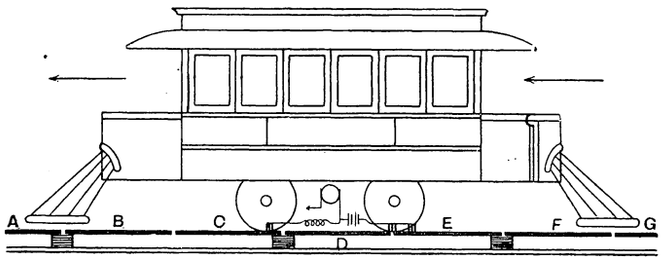

FIG. 3.—General Arrangement of Wynne System, showing Sectional Contact Rail and Diagram of Connections.

the main conductor for a short distance back along the line to the next section of the contact rail. A double armature, C C, carries a copper contact wedge, D, which is thrust between the contact springs when either or both of the magnets are excited. A diagrammatic view of the system is given in Fig. 3, where seven sections or parts of sections of the mid-rail are shown, lettered A, B, C, &c. The sections A and B are not yet connected with the buried conductor; C and D are so connected, and E and F are just about to be cut out. When this is done the armatures fall back by gravity. The contact between the conductor and the section F is maintained by the magnet in series with section E. One forward brush contact and two rear brushes are shown. One rear brush would generally suffice; but the object of having two is to ensure the bridging between two sections, so that a good contact may be made with one before the other is broken. The current passes from these brushes through the motor, and thence by the wheels and tram-rails to earth. In event of the breaking of the circuit, whether in stopping the car, or when it has been allowed to run down hill, the contacts in the contact boxes fall open. To enable connection to be re-made two or three secondary batteries are carried on the car, and being arranged with a small resistance of about $\frac{1}{3}$ ohm, as shown in the diagram, are kept always charged.

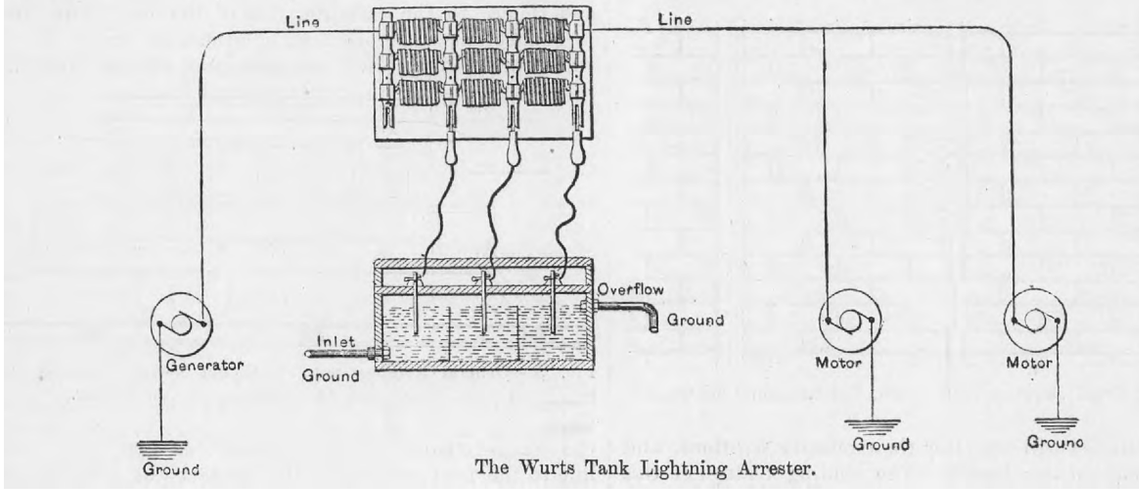
An experimental line has been laid on the works of the Electric Construction Corporation at Wolverhampton, and meets, we understand, with the full approval of Mr. Parker. We hope that Mr. Wynne will succeed before long in securing a line for the practical working of this system, which presents many advantages over the methods already in use.

THE WURTS TANK LIGHTNING ARRESTER.

An ingenious adaptation of Dr. Oliver Lodge's principle of "diluting down" electric discharges is described by Mr. A. J. Wurts in the *Electrical Engineer* of New York. In many American cities and towns, particularly in the Western sections of the country, it has, Mr. Wurts assures us, been common practice during thunderstorms to shut down the plant, pull down the trolleys and wait till the storm has spent itself. So far the ordinary spark gap arrester has proved of value, in that it has, without question, saved many thousands of dollars worth ofproperty.

Hosted by Google

Railway requirements are, however, better met by the "tank arrester," which consists of a coil of wire connected in the main circuit with several discharge circuits leading from different points in the coil to electrodes immersed in a tank of water, the latter being connected to the ground. Its construction will be understood by referring to the diagram. The coils made of 0000 copper wire, are nine in number, arranged three in series and three in parallel. The current capacity of No. 0000 wire is about 300 amperes, so that the capacity of the entire set of coils may be varied by any multiple of this number. The set shown in the engraving has a capacity of 900 amperes, and is mounted on a backboard, the dimensions of which are 32 × 20in. The tank is of wood, lined with galvanised iron, and its dimensions are 32 × 28 × 10in. The three electrodes are ordinary flat arc light carbons held in simple clamps, and the method of connecting these to the coils is clearly shown. The inlet is, of course, connected to the city main, and thus forms the best possible ground connection for the tank. The coils are connected in series with the station ammeter, and when thus connected will stand guard over the entire station.



The Wurts Tank Lightning Arrester.

The action of the combination is as follows:—All charges which may accumulate on the trolley line or feeders will be forced to pass through the coil before reaching any of the generators. The function of the coil is then to cause the fatal "side flash" to occur *there* rather than in the coils of the armature, and this is the more readily accomplished from the fact that there are several low-resistance paths from this coil to earth without the necessity of piercing any insulating material or jumping over the smallest air space. In other words, there is an exceedingly difficult path for the lightning discharges to reach the generators, and an extremely easy path for them to reach the earth. Furthermore, the fact that the line is directly connected to earth without the intervention of the air gap, offers a constant drain through which the static charge may dissipate itself, that is, the charge need not accumulate on the line till its intensity is sufficient to jump the spark gap of an ordinary lightning arrester.

Dynamo leakage is, of course, to be expected, and during the first stages in the development of this arrester the leakage was so excessive that the scheme would have been abandoned had it not been for the fortunate discovery that this leakage was reduced about 70 per cent. by the use of running water. With running water fed through a half-inch pipe at ordinary city pressure, the leakage amounts to 6 or 7 amperes at 500 volts. But in consideration of the almost certain protection that the arrester will afford, this loss of power sinks into insignificance, and in fact the leakage need only occur during thunderstorms, as the discharge circuits may be cut out at other times by pulling the plugs.

A number of these arresters have been in use during the past season in various parts of the States.

LOW CAPACITY TELEPHONE CABLE.

The bad effects of india-rubber and the excellent qualities of paper and air insulation for telephone cables have been recognised for some years; but numerous difficulties of construction have presented themselves, and many tests were necessary.

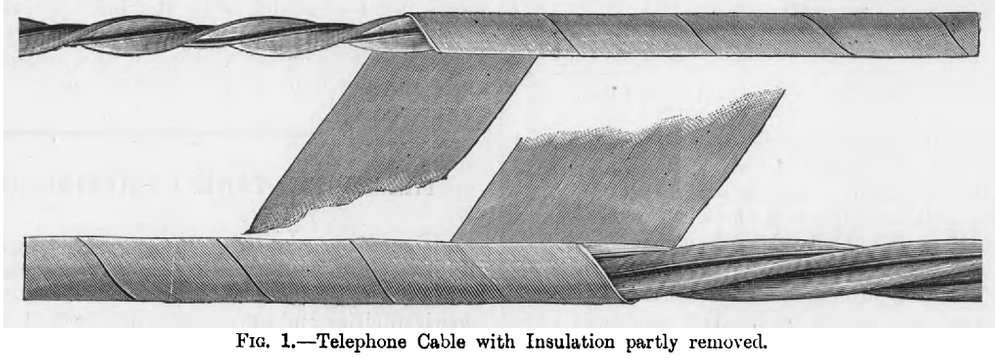


Fig. 1.—Telephone Cable with Insulation partly removed.

A new departure in telephone cable manufacture has, however, now been made in Europe by Messrs. Felten and Guilleaume, the well-known firm of electrical engineers and cable manufacturers. The accompanying illustrations (Figs. 1, 2, and 3) are self-explanatory; but a brief description of the construction of this cable will doubtless prove interesting. As will be seen from the drawings, the copper conductors of one metallic circuit are insulated from each other by a spiral barrier of paper; each circuit is then lapped with paper strips, either impregnated or unimpregnated, forming much larger air spaces than is possible by any other means. The necessary number of twin conductors to form the cable is then stranded in opposite directions, the whole being finally covered with lead; this may be braided externally if required. It will be

Hosted by Google

seen that there is the smallest possible contact between the copper conductors and the insulating material, and, consequently, the capacity is reduced to a minimum, and is guaranteed by the manufacturers to be less than 0·08 microfarads per statute mile with dry insulation, or 0·10 microfarads per statute mile with impregnated insulation; in reality the tests show much lower figures, whilst the insulation resistance is very high.

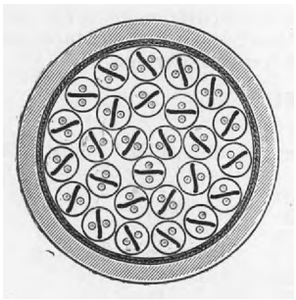

FIG. 2.—Section of Telephone Cable with Wires in pairs.

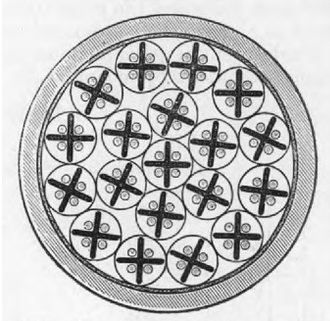

FIG. 3.—Section of Telephone Cable with Wires in "fours."

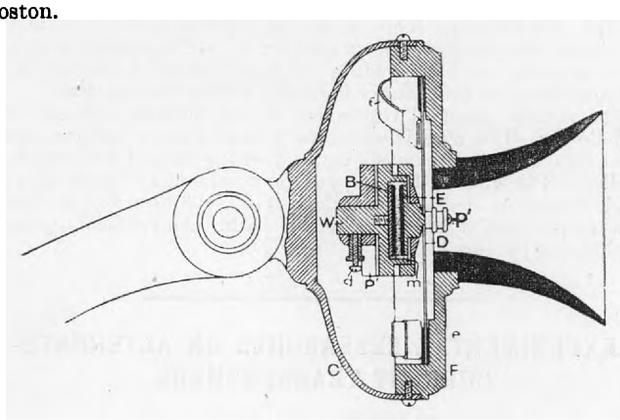
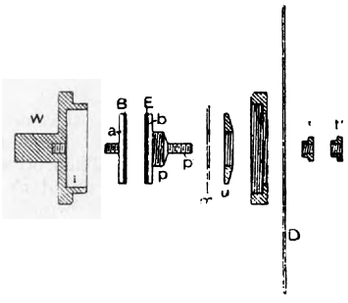
These cables are very light in weight compared with other types, and their volume is also considerably less, the diameter of one metallic circuit being about equal to that of a single conductor of existing makes; it follows, therefore, that a larger number of circuits can be gathered into a given area in this new type of cable. These cables can be constructed for metallic circuits in either "pairs" or "fours." With some modifications the same system is being applied to telegraph cables, where its advantages are especially favourable for long distance telegraphy.

THE "SOLID BACK" LONG-DISTANCE TELEPHONE TRANSMITTER.

The form of transmitter adopted by the American Telegraph and Telephone Company for their New York-Chicago line is known as the "Solid Back" transmitter. It is on the Hunning principle, and was devised by Mr. Anthony C. White, of Boston.





In this instrument it will be seen, says the *Electrical Engineer* of New York, the sound-receiving diaphragm D (*see* Figure) s attached directly to the disc E constituting the front or working electrode. B is a disc constituting the heavy back electrode, and there is finely-divided conducting material between the electrodes. A heavy metallic block, W, serves as a casing or frame for the electrodes and the finely-divided conducting material, being chambered to receive them. The finely-divided material, as in other instruments of the button type, is anthracite carbon, and the two electrodes E and B are discs of carbon. The walls of the chamber in the block W are lined with gummed paper, to prevent the short-circuiting of the instrument. It will be observed that there is a considerable space around the periphery of the two electrodes E and B to receive the finely-divided conducting material out of the direct path of the electric current. This construction prevents the clogging of the finely-divided material between the working electrode E and the walls of the chamber W that takes place when that electrode substantially fills the chamber.

The carbon electrode B is secured to the back on the bottom of the chambered block W by means of a brass disc *a*, soldered to the electrode and secured into the block. The front electrode E is soldered to a similar disc of brass, *b*, which by a threaded boss or pin, *p*, and nut, *u*, is secured to the inner face of a mica disc, *m*, that in turn is clamped to the sides or rim of the chambered block W by a threaded sleeve, *c*, serving to confine the finely-divided conducting material within the chamber of the block. The flexibility of the mica permits the front electrode E to have a piston-like movement in the chamber. The entire button, it will be seen, is secured by a set-screw, *d*, to a heavy brass bridge-piece, P', whose ends in turn are set into the metallic frame F of the receiving diaphragm, which, with its dampening and insulating ring, is held in place by means of padded springs, *f*. The frame F is set in a metallic cup-shaped outer casing, C.

ALLOYS FOR RESISTANCE COILS.*

BY DR. ST. LINDECK.

In a previous article I briefly discussed the results of the researches instituted with a view to the construction of resistances, having the utmost possible constancy. The first alloy tried with this in view and considered as perfectly suitable was "patent-nickel"—25 per cent. Ni, and 75 per cent. Cu. Although the temperature coefficient of this substance is only about one-half of that of German silver it is nevertheless necessary to take into account in all measurements having any pretensions to accuracy the relation of its specific resistance with the temperature.

In 1889 Mr. Weston, of Newark (U.S.A.), observed that the resistance of the alloys of manganese and copper, or manganese, nickel and copper scarcely changed at all with the temperature. However, the researches of Mr. Weston do not appear to have led to any really practical result; at any rate I do not know whether such alloys have been employed on a large scale in the making of resistances in the United States. Even Mr. Weston himself does not appear to have made much use of his important discovery.

The Reichsanstalt took up his work and succeeded in obtaining results of interest at the same time from the practical and scientific point of view. A whole series of alloys, some composed of copper and manganese, and others of these two substances associated with nickel were submitted to experiment. It was found that the mere addition of 4 per cent. of manganese to pure copper reduced the value of the temperature coefficient to that of the patent nickel without exhibiting, however, any characteristics worthy of note. If the proportion of manganese was raised to 10 per cent. the curve showing the modifications of the resistance with the temperature took a more interesting form, which I shall refer to more in detail later on. The specific resistance of the alloy increases with the proportion of manganese; the resistance of one of these alloys consisting of 30 per cent. manganese and 70 per cent. copper, exceeded 100 microhms per cubic centimetre. Alloys with a higher proportion of manganese could no longer be drawn.

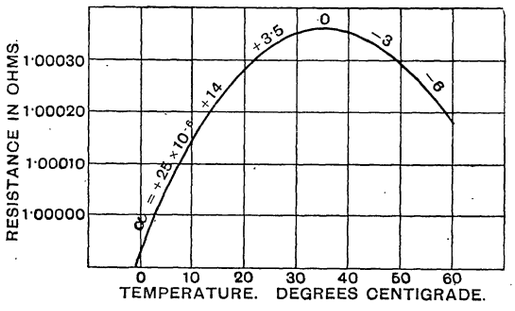
The alloy, the stability of which as a resistance has been tested during several years, and which is at present in commercial use under the name of *manganin*, is composed of 84 per cent. copper, 12 per cent. manganese, and about 4 per cent. nickel. Its specific resistance is 42 microhms per cubic centimetre. In the annexed diagram, in which temperatures are plotted as abscissæ, and the values of an accurate resistance equivalent to the ohm are plotted as ordinates, shows the changes in the resistance of manganin with temperature. Between 0° and 10°C. the temperature coefficient has the value of 0·000025. As the temperature rises this value

* From *L'Électricien*.

Hosted by Google

decreases, and between 30° and 40°C. the change of the specific resistance with the temperature is finally no longer sensible. After this the resistance begins to diminish as the temperature rises, so that the *temperature coefficient becomes negative*. We are, therefore, in the presence of the interesting case of a metal exhibiting properties which we have hitherto been accustomed to connect with electrolytes. As the reader may ascertain for himself by inspecting the diagram, the absolute values of the temperature coefficients are so small that in all cases where the highest accuracy is not required the temperature coefficients of manganin may be taken as zero. In fact, it is necessary to use very sensitive instruments and methods to show any change at all of the specific resistance with temperature. In order to make sure that the resistance always assumed the same value for the same temperature, in other words, to show that there was no hysteresis in the relations of these two quantities, some points of the curve were determined in ascending and others in descending the scale of temperature, and they were frequently repeated. No deviations were discovered which exceeded the limits of errors of observation. We may, therefore, consider it as settled by these measurements and observations, frequently repeated with different manganin resistances, that this peculiar behaviour is a constant physical property of the substance.

It has already been shown that rise of temperature has a durable effect on the resistance of coiled wires, and also of such wires as have not been submitted to a higher temperature. Manganin behaves in this respect like the alloys free from zinc, patent nickel, for example ; if we heat a coil composed of one of the two elements for the first time, the resistance is permanently lowered. For this reason it is necessary to eliminate these permanent changes from a coil intended to be used in tests similar to those described above. This is attained by submitting the coil as soon as wound to a temperature of 140°C. for five hours. Indeed, we ought naturally always to take this precaution in such investigations, no matter what material we are working with.



As we can see by the diagram, a manganin coil attains maximum resistance at a particular temperature. This maximum is not always attained at the same temperature by different wires. We know that the electrical properties of wires vary slightly with their dimensions ; moreover, the slightest difference in physical quality has an effect. Frequently the temperature of maximum resistance is found to be somewhat lower, especially in the case of wires larger than those in ordinary work, than is the case with the wire the curve of which is shown in the diagram. The assumption of invariability of resistance for the fluctuations of temperature usual in a room is a correct one. The fact that the maximum resistance of manganin is obtained at a temperature not very far off the average temperature of a laboratory was the reason which stimulated the Reichsanstalt to support its production on a commercial scale.

The two tables below give some data with regard to the constancy of manganin resistances. Table I. comprises the results of measurements made on a resistance of about 3 ohms, which was employed to determine the electromotive force of a normal Latimer-Clark cell by the aid of a silver voltameter. A current of half an ampere flowed through the resistance for one hour in each experiment. The resistance was used more than fifty times in this way. The table shows that the resistance has not varied in an appreciable degree in two and a-half years. Owing to its shape, the resistance is not capable of being measured more accurately.

Table I.

——	Ohm.	——	Ohm.
6/I 1890	2·9998	22/VII 1891	2·9996
15/IV „	99	9/II 1892	98
12/II 1891	98	17/VII „	96

Table II. shows the differences existing in the values of four one ohm resistances of precision, made in July of last year. A short time after we undertook the work of comparing the resistances with each other, and of measuring their absolute values. These comparative values did not possess quite the same accuracy as the values now given. Nevertheless, the fact is ascertained that *the greatest changes of resistance which can have taken place within the year amount to 0·005 per cent.* When we remember that resistances made in the ordinary manner undergo a maximum amount of alteration in the first year after winding, the assertion that the manufacture of wire resistances has been considerably improved by the researches carried out by the Reichsanstalt may be considered as proved. The following data refer to a temperature of 18°C., the differences between the resistances marked I. to IV. are given in *microhms*. The asterisk denotes that the measurements were made by the differential galvanometer method; the other measurements having been made by means of the Wheatstone bridge.

Table II.

——	December, '91.*	February, '92.	July, 1892.*	July, 1892.
I.—II.	-121×10^{-6}	−124	−117	—

II.—III.	− 14	− 15	− 12	−16
II.—IV.	+ 41	+ 39	+ 31	—
III.—IV.	+ 55	+ 53	+ 43	−48

A great advantage of manganin over all other alloys at present known is its extreme inferiority in thermo-electric power when in the presence of copper. Whilst for German silver, &c., the thermo-electric value is between 20 and 30 microvolts per degree Centigrade, for manganin it is only 1 to 2 microvolts, a circumstance to be seriously considered in measurements of precision.

In concluding this account of the investigations of the Reichsanstalt in this direction, I should mention that a series of alloys was tested, which, like patent nickel, was composed of nickel and copper only, in different proportions. The result of these investigations goes to show that without the addition of manganese we can obtain very low temperature coefficients. An alloy of about 50 per cent. copper and 50 per cent. nickel has a temperature of between 0·003 per cent. and 0·004 per cent. per degree Centigrade. Unfortunately this material, known in commerce by the name of *constantan*, is but little suited for resistances of precision, owing to its thermo-electric behaviour in the presence of copper. Constantan has a thermo-electromotive force of 40 microvolts per degree Centigrade in the presence of copper, and thus greatly exceeds in thermo-electric power the Iron-German silver couple so frequently used.

In the open air manganin does not do well. Its use is not to be recommended in cases were bare wires are employed, especially if there is likely to be a great generation of heat by the current. Moreover, a few precautions must be observed when drawing the material, since manganin is more easily oxidisable than copper and nickel. On the other hand, as soon as covered wires are employed manganin surpasses all known alloys ; in fact, manganin is almost without exception employed in the manufacture of resistances by German firms, in the manner indicated by the Reichsanstalt.

The normal standard resistances of the Reichsanstalt are made as follows :—The wire is wound on a metal tube, which, to ensure good insulation, is previously covered with a strip of silk soaked in shellac. The wire is then slipped on a bobbin, and again given a thick coating of shellac, after which it is submitted for five hours to a temperature of 140°C. in an air bath. An artificial *ageing* is in this way produced.

EXPERIMENTAL RESEARCHES ON ALTERNATE-CURRENT TRANSFORMERS.†

BY J. A. FLEMING, M.A., D.SC., F.R.S.

(Continued from page 102.)

III.—*Experiments with the Three-Ammeter Method of Measuring Alternating-Current Power.*

10. We next directed our attention to that modification of the voltmeter method suggested by the writer, and which involves current measurements instead of pressure. Theoretically, this method requires three ammeters, A_1, A_2, A_3, arranged in connection with the transformer under test, as shown in Fig. 6. In putting this method into practice we found it necessary, in the first place, to scheme some simple method of regulating the P.D. at the terminals of the transformer under test. This was accomplished as follows : —A 10-H.P. transformer had its primary, or fine-wire, circuit inserted in series with the primary current of the transformer under test. The secondary, or thick-wire, circuit of the 10-H.P.

† Abstract of a Paper read before the Institution of Electrical Engineers on November 24, 1892.

Hosted by Google

transformer was closed through a variable resistance consisting of 15 to 20 plates of battery carbon three inches square and a quarter of an inch in thickness, pressed together more or less by a screw clamp. By suitably compressing these plates we were able to regulate with great nicety the secondary current of the 10-H.P. transformer, and hence to adjust the resultant impedance of the primary circuit of the 10-H.P. transformer. The volts at the terminals of the transformer under test could then be kept perfectly constant, irrespective of slight variations due to the dynamo. As a non-inductive resistance we employed a series of 50-c.p. incandescent lamps. We then found that, working under these conditions, we could dispense with the third ammeter, A_3, and make one measurement once for all of the current taken by this series of lamps at 2,400 volts. Finally we reduced the method to the use of a single ammeter, as follows :—An ammeter was put in the primary circuit of the transformer under test, and the P. D. at the terminals of this transformer was kept constant at 2,400 volts. A series of incandescence lamps (generally 24 100-volt 16 c.p. lamps) was joined across the primary mains, and two readings of the ammeter taken—a first when the row of lamps was between the ammeter and transformer, and a second when the ammeter was between the lamps and transformer. An independent determination was made of the current taken by the lamps. These changes of position of the ammeter were made by mercury cup connections, so as to avoid at any time actually breaking the primary circuit. It will be easily seen that this single-ammeter method poss sses

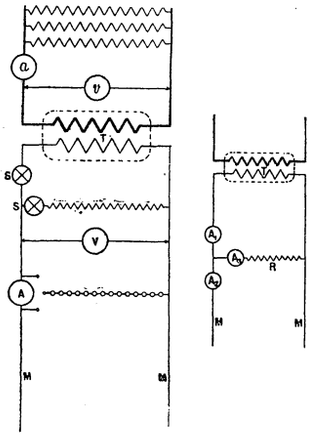

FIG. 6.—Plan of Connections for Ammeter Method.

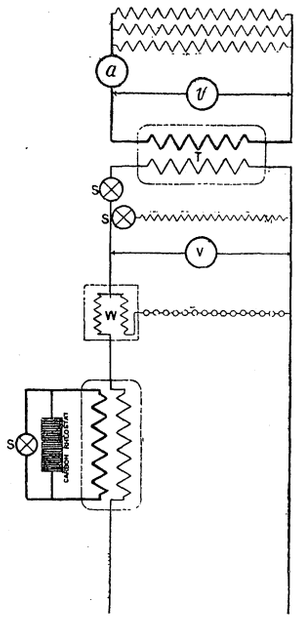

FIG. 7.—Connections of Dynamometer Wattmeter Method.

all the advantages, whatever they are, of the three-ammeter method, and is much simpler to work. The conclusions arrived at with respect to this ammeter method is, that ordinary commercial ammeters do not enable us to determine the currents with anything like the accuracy necessary when we are operating on open magnetic circuit transformers at no load. It would certainly be necessary to be able to read currents of magnitudes from 0·25 to 5 amperes to the third decimal place, and that is not in general a practicable matter by commercial instruments.

Table IX.—Ferranti Transformer (1885 *pattern*).—No. 747. Power, 5-H.P. Secondary volts, 100. Frequency used, 81·6 periods per second. Average final temperature of transformer=212° F. [Table XIII. shows that the primary amperes rose from 0·05 to 2 775. The secondary amperes rose from 0 to 64·748. The secondary volts fell from 101 to 98·6. The total power taken up in the transformer rose from 95 to 214.]

Table XIV.—Westinghouse Transformer.—Primary volts, 2,400 (kept constant). Secondary volts at no load=101·0.

[Table XIV. shows that the primary amperes rose from 0·05 to 2·775. The secondary current rose from 0 to 64·74. The primary copper losses rose from 0 to 45·8, and the secondary copper losses from 0 to 45·3. The real primary watts rose from 95 to 6,598, and the secondary primary watts rose from 120 to 6,660. The power factor varied between 0·79 and 1·03.]

IV.—*Experiments with the Dynamometer-Wattmeter Method of Measuring Alternating Current Power.*

11. Dissatisfied on the whole with the practical results and difficulties of the voltmeter and ammeter methods, attention was next turned to the employment of the dynamometer wattmeter as an instrument for the measurement of the power given to the primary circuit of transformers. There is no need to recapitulate well-known facts about the use of such an instrument for this purpose. It is well understood that a wattmeter or dynamometer with independent series and shunt coils can be used for this purpose, provided that the shunt circuit has a practically zero time constant, and the only difficulty which presents itself in passing an opinion on the suitability of any particular two-circuit dynamometer for this purpose is that of knowing whether the shunt circuit really *is* practically so far free from sensible inductance or capacity as to make this the case—and this, as our experiments show, must not be taken for granted without investigation. Two wattmeter dynamometers were provided. The first consisted of a Siemens dynamometer of the usual pattern, intended to be used as an ammeter for currents of 0·2 to 4 amperes. The fixed coil consisted of a few dozen or so turns of wire, and the moveable coil of four turns. We arranged the connections so that it could be used as a wattmeter, the fixed coil being the series coil, and the moveable coil of four turns being put in series with 24 100-volt 50-c.p. incandescent, or also with two rows of 24 16-c.p. lamps arranged in parallel, and this arranged as a shunt circuit. Contrary to the usual practice we had then a wattmeter in which the shunt circuit carried the larger current. This circuit was traversed by a current of from 1·8 to 2·94 amperes when placed across 2,400-volt mains, according to the group of lamps used.

This dynamometer wattmeter had then a shunt circuit consisting of the 24 series of lamp filaments *plus* the four turns of wire on its moveable coil. It had, therefore, a very small inductance. This wattmeter was calibrated by applying it to measure the known power taken up in our standard resistance. The six coils of our No. 1 resistance, each consisting of about 1,600 ohms, were arranged, two in series and three in parallel, across 2,400-volt mains. The current through these resistances was measured by a Kelvin deci-ampere balance, and found to be 2·230 amperes ; the P.D. between the mains was measured by the Swinburne voltmeter, and found to be 2,400 volts, and kept at that value by a regulating transformer with carbon resistance on the secondary circuit (*see* Fig. 7) ; and from these measurements the power taken up in the resistance was known. It was 5,357 watts. The dynamometer wattmeter was then arranged so as to measure the known power being absorbed by this resistance, and the constant of the wattmeter thus determined. A torsion of 175deg. of the dynamometer head was found

Hosted by Google

to be required when the resistance was absorbing the above power. This constant was frequently determined. The value was close to 30·6 watts per division of the scale. It will be seen, therefore, that we were employing a wattmeter which, although it absorbed considerable power in its own shunt circuit, had a range of measurement from 12,000 watts down to about 10 or 12 as a minimum visible.

We found it essential to standardise the wattmeter on the largest power-absorbing arrangement possible, so as to get the greatest possible wattmeter scale reading on a known power-absorption in determining the instrumental constant. For if a small power reading was taken, then any error in the scale reading was multiplied up in getting the watts corresponding to a larger scale reading taken from a value of the constant, and sensible errors introduced.

In addition to this instrument, Mr. Swinburne provided two of his own non-inductive wattmeters. In this last instrument the shunt circuit consisted of a small bobbin of a good many (probably a hundred or more) turns of fine wire, having a resistance of about 300 ohms. In series with this externally, and forming part of the wsttmeter shunt circuit, were two doubly wound wire resistances in brass boxes; having a total resistance of about 100,000 ohms, assumed to be practically non-inductive. Provided with these wattmeters, we proceeded to make a series of tests on various transformers of the power absorbed when the transformer was doing secondary work of various loads. The results are embodied in the series of tables below. In each case the Siemens dynamometer, called hereafter the "dynamometer wattmeter," was standardised on the inductionless resistance when absorbing about 7 H.P., and then, having obtained the constant, its readings were taken when placed on the primary circuit of the transformer. The column headed "Power taken up by Swinburne Wattmeter," records the observations made with the first wattmeter he sent having an outer case of brass.

In Table IX. are given the figures of observation for the 5-H.P. (1885 type, old form) Ferranti transformer. The transformer had gradually increasing loads of lamps put upon its secondary circuit, and whilst the power, W_1, supplied to the primary was measured by the dynamometer wattmeter, that given up by the secondary, W_2, was measured by a Kelvin balance and electrostatic voltmeter placed on the secondary circuit. We measured also the primary current value in amperes corresponding to each definite load on the secondary circuit. We obtained, therefore, for every transformer, the volts, or P.D. across both terminals, the ampere current, and the watt output of the secondary circuit, and at the same time the ampere current and power absorbed in watts by the primary circuit; and hence the difference between W_1 and W_2, or the power lost in the transformer, is also known for each secondary load. Finally, also, the ratio of W_2 to W_1 in percentages can be calculated, and gives us the efficiency. In all these experiments the P.D. on the primary terminals was kept carefully constant at 2,400 volts, and the constant of the primary wattmeter checked at the beginning and end of each series of observations.

A series of tests of this kind was made on each one of the following 10 transformers:—A Ferranti 5-H.P. (1885 type), a Ferranti 5-H.P. (after having had the primary and secondary circuits both replaced by others of double the length), two 15-H.P. (1892 type) Ferranti, a 20-H.P. (1892 type) Ferranti, a Westinghouse 6,500-watt (the same transformer used by Dr. Hopkinson in his recent tests), a Mordey-Brush 6,000-watt, a Thomson-Houston 4,500-watt, a Kapp 4,000-watt, and a Swinburne 3,000-watt "Hedgehog." For each transformer was determined the currents and terminal potential differences corresponding to the various stages of secondary load from no load up to the full nominal output of the transformer, and at the same time the power, W_1, given to the transformer primary circuit, and the power, W_2, taken off from the secondary circuit. The "total lost watts," $W_1 - W_2$, and the efficiency, or ratio W_2/W_1, corresponding to each secondary load, were also calculated. From the known or measured value of the resistances of the copper circuits (taken when the transformer was warm) and the measured currents we could calculate the copper losses ($C^2 R$ losses) in both circuits, separately and together, to the nearest integer, omitting fractions of a watt in most cases; and from the primary volts and current we obtained the value of the "apparent watts" given to the transformer at each stage; and from the "apparent" and "true" watts given to the primary circuit we could deduce the power-factor corresponding to any secondary output. The values of the secondary terminal P.D., or volts, gave us also the "total secondary drop" at each load, and from the resistances and currents could be found the "copper drop," or volts lost by resistance. The observations and calculations for each of the 10 transformers tested are given in full in Tables IX. to XXIX., inclusive, which sufficiently explain themselves.

Table XV.—Ferranti Transformer (1892 *pattern*).—No. 2,194. Power, 15-H.P. Secondary volts, 100. Frequency used, 81·6 periods per second. Volts on primary circuit (V_1)=2,400 (kept constant). Primary circuit resistance=6·45 ohms. Secondary circuit resistance=0 0134 ohm.

[Table XV. shows that the primary amperes rose from 0·076 to 3·715, when no further readings were recorded. The secondary current rose from 0 to 114·63, and the secondary volts fell from 100·4 to 97. The total power taken up in the transformer varied between 149 and 570.]

The power factor rose from 0·07 to 0·84.]

12. The results of these numerous observations are set out graphically, and thus represented to the eye, in a series of diagrams, shown in Figs. 8 to 45 inclusive. For each transformer four diagrams have been prepared.

The first shows the "total lost watts" curve, or $W_1 - W_2$, plotted as a curve in terms of the corresponding secondary output W_2; and on the same diagram is given a curve showing the total copper losses (C^2R) in the transformer in both circuits together. Hence the difference of the ordinates of these two curves gives the value of the losses other than those due to ohmic resistance in the transformer. The second diagram shows the value of the two currents, primary and secondary, plotted in terms of the secondary output. Since all the closed magnetic circuit transformers tested had a transformation ratio and windings in the ratio of 24 to 1, the primary current and 1-24th part of the secondary current are plotted together on the same scale. The third diagram gives the efficiency curve. The efficiencies in per cents. corresponding to decimal fractions of the full secondary output, are calculated from the "total loss" curve and then drawn. Hence they are all comparable, and we can see at a glance the percentage efficiency corresponding to loads of one-tenth, two-tenths, &c., of the full secondary load. The fourth curve is the "secondary drop" curve, and gives the "total observed drop," the "drop" due to secondary and to primary resistance, and the surplus or "leakage drop" due to leakage of induction, all plotted in terms of the secondary output. The efficiency values are tabulated in Table XXX. for the different fractions of full load for all the transformers.

13. It is desirable to make one or two remarks about each transformer, and draw some general conclusions.

Ferranti Transformer, 1885 *type, 5 H.P.* (Tables IX. and X., Figs. 8, 9, 10*, 11*.)

It is obvious that this transformer is, in comparison with modern ones of the same size, very wasteful of energy in transformation. But we must bear in mind that in 1885 little or none of our present knowledge about iron core energy losses existed, and it is not to be wondered at that its design is imperfect, according to modern views. The immense core loss of 549 watts (540 by three-voltmeter method) makes it possess a low efficiency at all loads, and gives it a flat efficiency curve. Its small copper losses, however, make it remarkably good in regulation, it having only 2·4 per cent. of total secondary drop. It is hardly necessary to say that Mr. Ferranti's present type of transformer is a vast improvement on these, and holds its own with the best now made.

Ferranti Transformer, 1885 (*re-wound*). (Tables XI. and XII., Figs. 8, 12, 13*, and 14*.)

The effect of doubling the length of both the primary and secondary circuit is shown in the curves of this transformer. The total internal losses are halved, but the copper losses and "secondary drop" about doubled.

Ferranti Transformers, 1892 *type*, 15 *and* 20 *H.P.* (Tables XV., XVI., XVII., XVIII., XIX., XX. Figs. 19*, 20, 21*, 22*, 23, 24*, 25*, 26*, 27, 28*, 29*.)

These new transformers of Mr. Ferranti's are exceedingly good transformers. The total loss on open circuit of the 20-H.P. is only 1·3 per cent. of the full secondary output. The maximum efficiency is 97·1 per cent., and the efficiency at one-tenth of full load is 85 per cent., whilst the total secondary drop is only 2·1 per cent.

Two sets of curves are given for the transformer of 15 H.P. size. In two transformers tested there was a difference in the winding which resulted in the total internal loss being greater in one than in the other. In the transformer having the greatest total loss the copper losses (C^2R) are least, and the "secondary drop" diminished, therefore, about 1 per cent. The efficiency curve of all these transformers is very square-shouldered, owing to the high efficiency (about 85 to 87 per cent.) at one-tenth of the full secondary load.

Westinghouse Transformer, 6,500-*watt*. (Tables XIII. and XIV. Figs. 15, 16, 17, and 18.)

This transformer was one of the pair tested by Dr. J. Hopkinson by his elegant differential method. His results are recorded in *The Electrician* of June 24 and July 1, 1892. Employing a method depending upon the graphic description of the instantaneous curves of current and E.M.F., Dr. Hopkinson deduced the power lost in the transformer at no load, quarter, half, and full load. Hence the corresponding efficiencies. The same quantities were given me independently as determined by the manufacturers from tests made at Pittsburgh. These are here collected with my own results for comparison. Dr. Hopkinson's results are placed in the column marked H, those of the manufacturers in column P, and my own in column F; and it will be seen that we all substantially agree in the values of the quantities measured :—

Quantities Measured.	P.	H.	F.
Watts lost at no load	91	114	98
Watts lost at half load	—	149	141
Watts lost at full load	—	236	209
Secondary drop at full load	2%	2·2%	2·4%
Efficiency at half load	96·4	96%	96%
Efficiency at full load	97%	96·9%	96·9%
Total copper losses (C^2R) at full load, in watts	104	—	93

It is clear, therefore, that there is no serious disagreement between us, and that this transformer is a very excellent instrument. Its maximum efficiency is just upon 97 per cent., and its efficiency at one-tenth of full load is nearly 85 per cent.

The loss in power at no load is by my figures 1·46 per cent. (by Dr. Hopkinson's 1·75 per cent.) of the full secondary output. The core of this transformer is made of a high quality of pure steel, the plates being slightly oxidised to insulate them for eddy currents.

Mordey Transformer, 6,000-*watt*. (Tables XXI. and XXII. Figs. 30*, 31, 32*, and 33*.)

Two transformers of this size were tested. In one the three-voltmeter method showed the power loss at no load to be 125 watts; in the other the dynamometer wattmeter gave 148 watts. If we take the mean of these results, we get 136 watts as the open-circuit loss. This is 2·27 per cent. of 6,000 watts.

We found the "total secondary drop" between no load and full load to be 1·9 per cent. of the voltage at no load. In the official publications of the Brush Company the manufacturer's figures, for this sized transformer, for the open-circuit loss as a percentage of full load is given as 1·82 per cent., and the percentage total drop is 2·25 per cent. ; but these figures refer to the 6-kilowatt transformer worked at a frequency of 100 ∿ and transforming from 2,000 to 100 volts. As the transformer tested by us had a transformation ratio of 24 to 1, and worked at 83 ∿, it is a question how far the official figures may be applied to it; but, at any rate, our determinations agree with those of the manufacturer

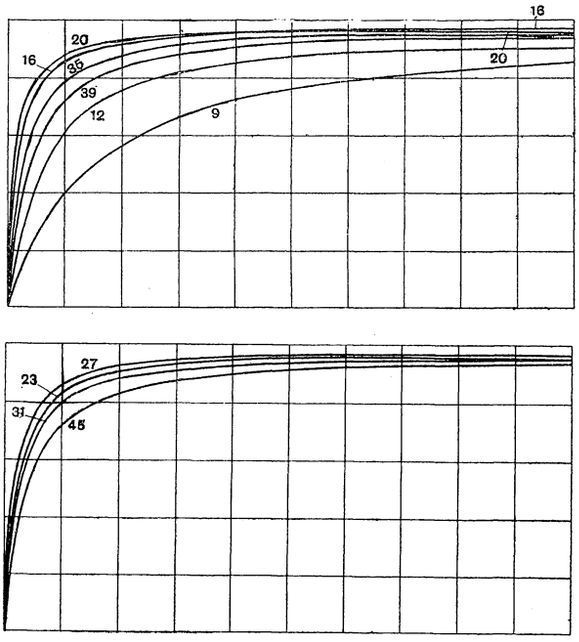
very fairly in assigning a value of not far from 2 per cent. both to the open-circuit loss and total secondary drop.

According to our observations this transformer takes rank as one of the best for regulation, having regard to its size and its open-circuit loss. The maximum total copper loss (C^2R loss) is 117 watts, and the maximum total loss at full load is 311 watts. The maximum



Efficiency Curves. The number against each curve refers to the Figure mentioned in the paper.

efficiency is close to 96 per cent., and the efficiency at one-tenth of full load is 80 per cent. These figures are, perhaps, not quite comparable with those of the 20 to 1 6,000-watt transformer worked at 100 ~, but they are, at any rate, not very different from the values of the similar quantities given by the manufacturers for this last transformer.

We shall deal more at length presently with the important question of the constancy of the iron losses at all loads, which the observations on this tranformers bring out most clearly.

(To be concluded.)

ELECTRIC LIGHTING AND TRACTION NOTICES.

The time for giving official notice in the *London Gazette* of Private Bills to be presented to Parliament next Session, and of all Provisional Orders, expired on Wednesday. From the following list of notices relating to electric lighting and traction enterprises it will be seen that there are 17 traction notices and 20 electric lighting notices. Last year the figures were 15 and 34 respectively. Of the grand total of 37 notices no less than 17 are given by Local Authorities, who seem as anxious as ever to retain their grasp on electrical enterprise.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, December 2nd.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Ordinary Meeting. Paper to be read:—"Water-tube Steam Boilers," by Harry Fraser.

MONDAY, December 5th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting. Paper to be read:—"The Shortlands and Nunhead Railway," by A. G. Drury.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture. I., 3, "The Generation of Light from Coal Gas," by Prof. Vivian B. Lewes.

TUESDAY, December 6th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed:—"The Manufacture of Small Arms," by John Rigby, M.A. At this Meeting the first monthly ballot for Members for the session will be taken.

WEDNESDAY, December 7th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read:—"The Chicago Exhibition, 1893," by James Dredge.

THURSDAY, December 8th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Annual Business Meeting, and discussion on Dr. J. A. Fleming's Paper on "Experimental Researches on Alternate Current Transformers."

FRIDAY, December 9th.

PHYSICAL SOCIETY.

5 p.m. Ordinary Meeting. Papers to be read:—(1) "On Colour Vision," by W. B. Croft; (2) "On Japanese Magic Mirrors," by Prof. S. P. Thompson; (3) "Reflection from Diffusing Surfaces," by Dr. Sumpner.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read:—"Electric Light Cables," by E. S. Franklin.

STEEL-PLATE PORTRAITS

Of Willoughby Smith, W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, G.C.M.G.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz, Prof. W. E. Ayrton (President of the Institution of Electrical Engineers), Lord Rayleigh, F.R.S., and Cyrus W. Field, have been issued as Supplements to "THE ELECTRICIAN."

A few Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, 4s. 6d, carriage paid (U.K.)

NOW READY.

Volume XXIX. of "THE ELECTRICIAN," price 12/6; post free, 13/6 abroad carriage extra.

Cases for binding Volume XXIX., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

ELECTRIC TRACTION.

"There is surely no greater wisdom," wrote BACON, "than well to time the beginnings and onsets of things . . . first to watch and then to speed," and by carefully watching what others are doing, and by using every caution in the beginnings and onsets of the art of Electric Traction in this country, we shall doubtless arrive at not only speed, but at comfort and economy. Though but few electric lines have been laid in England, no greater variety can be found even in America; almost every system has been tried, excepting, perhaps, primary batteries and drehstrom; and while the trolley is the accepted solution of the problem in the United States, only three examples, and these, the most recent, are to be found in this country. We are not prepared to admit that because little success has attended other efforts, we have been forced to this unsightly and by no means simple system; but if, as its advocates are ever ready to assert, it be really more economical both to erect and to run, there is hope that experience will be gained in such matters as are common to all systems, and that when a margin of profit has thus been realised, some

Hosted by Google

more civilised methods may become possible. As a choice between evils the experimental line in Bradford is vastly preferable to the noisy, dirty, and hideous steam trams; as a convenient means of access to the pleasure grounds of Roundhay, the trolley wires and posts in the suburb of Leeds may be forgiven, while those parts of South Staffordshire, in which the latest line has been erected, are long past spoiling. Much as we dislike the idea of trolley lines along any roads or streets in which the least regard is paid to appearance, we must confess that public taste has already given way to the introduction of tram lines with tame resignation where once they were stoutly opposed, and that it is quite possible that the trolley line may some day be seen along Princes-street, Edinburgh, or the High in Oxford, or any other equally fine street, if such there be, which has been disfigured by the tram and its lines. Fortunately there are other systems, little if anything behind the trolley in expense of working, and perhaps not much more costly to equip; and of these we may hope to see some examples at no distant date.

The first electric tram line was one of the few true trolley lines that have been tried; we refer to the Siemens' car at the Paris Electrical Exhibition of 1881. Two conductors were erected on posts alongside the track, and on these two collectors ran, being attached to the car by flexible wires. A return has been made to the general arrangement of this method in the adoption of a side conductor on the South Staffordshire line, a trolley rod being used instead of the flexible cords. The other features of the South Staffordshire line which we have recently described call for no special comment. With the exception of this detail there is little to distinguish it from the common practice in America. Our requirements and habits as well as our climate and the price of labour all go to determine the value of rapid transit and the choice of a system of traction. While the dampness of the atmosphere renders the insulation of bare conductors rather difficult, we find that other countries have their peculiar drawbacks. It is a common custom in the Western States to stop all the electric cars as soon as a thunderstorm begins, since a far-spreading trolley line with all its concomitant network of slings, spans, strain wires or pull-offs, anchorings, duplicate guards, besides hangers, brackets, and frogs, all earthed at and through the car itself, is too strong a temptation for the lightning, and the traffic must be stopped and the trolleys released, unless, indeed, such protectors as that of Wurts are found to be efficient. In Montreal, again, the citizens were recently represented as delighted with the idea of having a tramway service in the winter, but it is now stated that a petition with 10,000 signatures has been sent to the City Council protesting against it, since the roads would be spoiled for sleighing.

For the streets of towns in which trolley wires will not be permitted, there is a considerable choice of closed or slotted conduit lines. The experience gained at Blackpool has been of great value in proving the practicability of a slot under very trying circumstances, but many closed conduit systems have been offered, and on an experimental scale they have been found to work with every promise of success. The names of Ayrton and Perry, Wheless, Hopkinson, Short and Naysmith, Pollock and Binswanger, J. Gordon, Holroyd Smith, Lineff and Wynne are connected with closed conduits. Three ways of making contact between a sectional contact rail and a buried conductor have been proposed—the weight of the car, electro-magnetic switches, and a picking-up magnet, carried by the car. The Wynne system, which is described in another column, is the latest development of these types, and the only difficulty that seems to present itself is the maintenance in working order of some 530 electro-magnetic switches per mile of line. The diving-bell cover will certainly go a long way towards protecting these devices from actual water, and it must be remembered that if one or two missed fire occasionally, the car would run on by its momentum.

In neither of the two books which are reviewed in our present issue, nor in any Paper before an engineering society, have the advantages or the possibility of constructing a variable gearing been discussed. We have thrown out a suggestion for such a gear in these columns, and a most promising and thoroughly mechanical design for an alternative double gearing was shown to us only this week. The use of a disc wheel as in an integrating instrument has been tried by the Conolly gas motor, but it is out of the question under a tramcar. The slipping friction clutch is a makeshift on unsound principles; it is frequently suggested, and the fallacy is as frequently pointed out, but the use of resistances and the waste of heavy currents through armatures in starting is as radically bad, clumsy, and wasteful a method as it is possible to conceive. The grouping of cells in various ways, when storage batteries are used, is better, for there is little or no waste of volts. Mr. Reckenzaun says that no engineer would be so foolish as to employ a 30 H.P. motor where a smaller motor would suffice, but a car with only a 4 H.P. motor cannot mount a hill, and thereupon he, like all other traction men, recommends two motors, and Mr. Holroyd Smith, to make doubly sure, uses four. Two motors, it is true, can be used to drive independent axles, and in the event of disablement of one, the other motor will see the car home somehow, but the same arguments might be applied to the design of a steam locomotive. What is really wanted to enable electric traction to compete with other mechanical systems—and the competition with cable lines promises to be very severe—is an equivalent to the expansion gear. A rather complicated arrangement of motor and dynamotor proposed by Ward Leonard, and independently hit upon by an English engineer, would work under a constant high pressure and generate on board the car whatever power was needed, wasting practically none. This is an electrical solution of the problem; but when there is a choice between a mechanical and an electrical method it will generally be found that the latter is the most attractive and complicated, though easy to design, while the former is more sure and trustworthy,

A renewed interest is being taken in electric traction, and several inventors and manufacturers are eagerly inquiring for openings. Storage battery makers in particular are striving to throw off the reproach of expense and other disadvantages under which accumulator traction has laboured. The Electrical Power Storage Company have several negotiations in hand, and the Epstein Electric Accumulator Company are supplying additional sets of batteries for the Birmingham Tramways and propose to undertake maintenance contracts at about $1\frac{1}{2}$d. per car mile. As a rule, however, the capital of Tramway Companies is so large, and the tenure of their lines is so short, that they find great difficulty in contemplating a change in their methods of traction. But while this may constitute a difficulty, it must not be forgotten that no stronger argument can be found for giving every attention to the development of electric traction, since the expiry of these tenures should be seized upon, affording as they will the most important opportunities for the introduction of new systems. The desirability of rapid transit and facilities for locomotion is becoming more and more manifest, and many a suburb owes its very existence to the services of trains, trams, or 'bus, which take its residents to their daily work.

REVIEWS.

Street Railways: Their Construction, Operation, and Maintenance (Trams). By C. B. FAIRCHILD. (New York: Street Railway Publishing Company, 1892.)

This large and well-illustrated volume claims to be "a handbook for those building or operating either electric, cable, horse, or elevated lines." By way of explaining to the old-fashioned Britisher what is meant by a street railway the title-page concedes the explanation—trams. A very useful book on traction might be written without a single illustration or even diagram, and the whole subject might most advantageously be discussed from general principles of design and management without entering into details, which, after all, only embody one way, and one particular way, of carrying out such principles under a certain set of conditions, many of which may not, perhaps, be found together in another example. The book before us attempts to cover electric, cable, horse, and purely mechanical traction; inclined roads, rack railways, elevated railways, car building, track construction, rules and regulations, bookkeeping and management. It is more than doubtful whether any one man could be found to write a useful and in any sense complete book on so wide a subject, using the word complete to denote merely that the various sections and sub-sections contain more than a casual example and give more than a mere smattering of the information which the reader may fairly expect.

The editor of such a journal as the *Street Railway Gazette* of New York has, undoubtedly, an ample stock of material whereon to draw; but by a mere compilation of examples, interesting as they may be to one who already knows something of perhaps one branch of the business, interesting because they tell him what is being done in allied branches, and not without attraction to the young engineer who may examine the results, the art of construction cannot be imparted without a proper examination of the general principles of design.

By way of making a good start, the author leads off with an introduction on the elements of electrical science, but it is quite inadequate to enable an intelligent engineer to understand the problems of electric traction. Trucks, gears, and motors are illustrated in profusion, but by engravings from photographs, showing outside views. The idea of such illustrations is to give the general arrangement, but the general arrangement cannot be understood even by the initiated unless it be accompanied by sections and elevations in a systematic manner. They tell the engineer little or nothing; makers are, of course, quite aware of this, and willingly give a photograph to be engraved when they grudge an outline tracing. Many illustrations appear to give a good deal of information, while they really give none, and in no case is this more marked than in perspective views from photographs of the under-frames of electric tram-cars, with motors and gear complete. They satisfy the general public, however, who think that if they cannot understand a jumble of tie-bars, wheels, and brake-gear with a motor or two half buried in the midst, it is their own fault. In the section devoted to electric traction stations we find illustrations showing in one case thirteen, and in another twenty-one, separate dynamos, but not a word about the design of such stations, or the reasons for a choice of a unit. We cannot expect to find any attention paid to the humble attempts at electrical traction in this country or on the continent, but we remark that worm gear is not even mentioned, and conduit systems are dismissed in three lines.

The second chapter, on cable lines, appears to be the best in the book. It contains copious illustrations of conduits and conduit frames, curve-pulleys, grips, cables, splices, &c., but we notice only one roller grip, that which is used on Brooklyn Bridge. Really fine direct-acting or rope-driving engines are used for this work, a great relief after the rows of little engines belted to dynamos, or to countershafts, in the first chapter. The chapter on horse traction, illustrated with plans and views of stables, may be passed over as having little to do with engineering; and the next one, on steam, compressed air, and gas, because it is very poor. Rack railways and "elevated roads" have little to do with trams, and need no comment. A long chapter deals with car-building, and here we have coaches and trucks innumerable. Some of the illustrations are intelligible to the engineer, and give a good idea of what has been done; but how these designs were arrived at, or to what special purposes they are suited, not a hint is given. The profile of car wheels, and the conditions governing the length of wheel base, are utterly neglected. Considerable space, on the other hand, is devoted to coach-painting, glass-embossing, and trimming. Track construction and road making are treated in a rather better style, but only one-half of a single sentence is allowed for the relation between wheel-base and minimum radius of curve. Twenty-nine quarto pages are filled with a collection of rules and bye-laws. Under rules for drivers we find, No. 12, a driver must not spit tobacco juice so that the wind will carry it on to the passengers, and No. 36 enjoins that on the Sabbath the bells on the horses must be muffled, and the speed reduced to a moderate pace when passing churches or their immediate vicinity. The book concludes with chapters on municipal licences and on book-keeping. This last is, perhaps, more useful than any other in the volume, and contains numerous examples of report forms, log sheets, and ledger rulings. These, however, are merely suggestive for the most part, since each manager must devise such details and not copy them. Having said all that he has to say, but having 47 illustrations of cars and 102 blocks of sundry appliances left over, the author prints them by themselves without comment. The whole book suggests compilation from advertisements and trade catalogues and newspaper notices, but is worth perusal by those who are interested in them and are already familiar with one or more branches of the important subject with which it deals, for some illustrations speak for themselves, and mutely tell the tale of construction and even of design to those who have already a fair knowledge of engineering.

Electric Traction on Railways and Tramways. By ANTHONY RECKENZAUN. (London: 1892.)

A book by Mr. Reckenzaun on electric traction cannot but command attention, and even though he describes it as an endeavour to summarise as concisely as possible the present state of electric traction, he takes too keen an interest in the work to content himself with a mere description of the methods and constructive details, which are to-day in use. The book contains an excellent elementary account of the principles which govern the design and working of electric lines, but it is very unequal. Dynamos, for example, are dismissed in a few words, possibly because no distinct type of machine or system of driving has been adopted; it is, nevertheless, an omission. The author apologises for departing from a systematic arrangement of chapters on account of new and interesting matter received at the last moment, but this is of minor importance compared with the disjointed arrangement of the introduction which contains much that is of importance. Prony-brakes with levers are rather out of date, and no dexterity is demanded in the use of a rope brake. Fleeming Jenkin's brake is described and leather is recommended for the cords. When, however, ropes are used, and spring balances are substituted for weights, all the old difficulties disappear. A few useful notes on motor efficiency are given in the first chapter, but make no claim for originality. The author has collected some valuable data on traction, and discusses the effect of inertia on starting, tractive force, increased friction on curves, calculations for gradients, and like matters, which, though common to all systems of mechanical traction, are completely ignored in the more pretentious book which we have just noticed.

In proceeding to the design of motors, the author quickly, and we think on very insufficient grounds, arrives at the conclusion that two motors ought to be employed. After a few pages on design, several types of motors are described, and these are followed by speed-regulating switches, and the various devices, each one in our opinion more clumsy than the last, by which electricians rather than electrical engineers have attempted to control the power developed by their motors. A good account is given of the principal systems of trolley and conduit lines, with many details of construction.

A chapter is devoted to secondary batteries, and, as might be expected, a large portion of it is concerned with the difficulties and causes of deterioration. After this a number of important

Hosted by Google

lines are described including those of Portrush, Bessbrook, City and South London, the projected Central London Railway and the Birmingham tramway. The next chapter is headed "Practical considerations relative to public convenience and general utility; advantages of electric traction," but on turning over a page or two we find ourselves in the intricacies of "bucking." There is a good deal worth reading in this chapter, but as there are but few paragraph headings or sections, and as each page of the book bears the headline "Electric Traction," it is rather difficult to find one's way in it. A number of tests of various lines, including load-diagrams of the City and South London line, are given. Some nineteen pages on the cost of working conclude the volume. It was not until we came to accounts of the Frankfort-Offenbach, and of the Halle Tramways, and recognised them as having appeared in Mr. Reckenzaun's Paper, read before the Institution of Electrical Engineers, that we recollected that such a Paper had been written, a sufficient proof, if one were needed, that the author has done something more than merely expand and add to that communication.

THE ABUSE OF LONG-LIVED INCANDESCENT LAMPS.

When incandescent lamps first began to come into commercial use, says M. Hospitalier in *l'Industrie Electrique*, people were content to estimate their value, on the one hand, by their *initial* consumption of energy in watts per candle, and by the *average* life guaranteed by the maker. Unfortunately, the specific consumption is one of the most variable of factors, according to the *régime* adopted and the qualities of the lamp. To get a clearer idea of the value of a lamp we must pursue our investigations further, and take into account the diminution of candle-power with time, the price of the lamp and its life, and the cost of electric energy. Endeavouring to bring in these different factors in a rational manner, Mr. Edward O'Keenan has evolved an analytical method, both ingenious and practical, which it may prove useful to describe, and, at the same time, indicate the singular result to which it clearly leads, namely:—*Consumers smash your old lamps after a few hundred hours' service!*

This conclusion, which has nothing in it displeasing to glow-lamp manufacturers, is justified by Mr. O'Keenan's method, which I propose to elucidate and apply to typical modern glow-lamps, making use of the figures given by M. Ch. Haubtmann in an interesting article entitled "Investigation of the Consumption of Incandescent Lamps,"* published in *l'Electricien* of September 24, 1892, p. 201. (*See* also *The Electrician*, September 30th, Vol. XXIX., p. 590.)

Mr. O'Keenan seeks to determine the moment in its existence at which a lamp should be broken up, and this moment he calls *smashing point*. This point is determined by plotting a certain number of curves showing the peculiar characteristics of a lamp, and enabling us to estimate its value at any instant of its existence from various points of view. All these curves are plotted with hours of service as abscissæ, and with the following quantities as ordinates:—

A. The electric energy in watts consumed at any instant.

B. Candle-power (Fig. 1).

C. Energy consumed (watt hours) since the lamp was put into service (*i.e.*, the integral of curve A).

D. The quantity of light produced by the lamp (candle hours) since it was put into service (*i.e.*, the integral of curve B).

E. The cost of the energy (in francs) consumed by the lamp since it was put into service. Curves C and E may be made one by a suitable choice of a scale of ordinates.

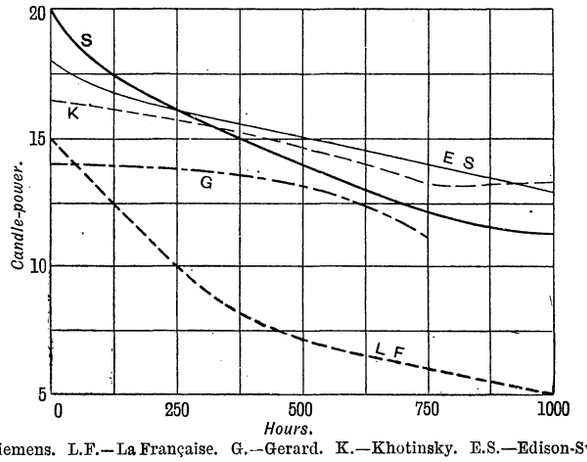
F. *Total* cost of the lamp (in francs) since being put into service; a curve which is obtained in raising the curve E by an amount equal to the price of the lamp.

* Certain qualifications having been put forward with regard to M. Haubtmann's figures, we only use them in this article to illustrate the method.

[To simplify the calculations and the construction of the curves I have taken the electric energy as costing 1 franc per kilowatt hour, and the lamp at 2 francs; figures which are, as a matter of fact, very near the actual truth in Paris.]

G. Specific cost (Fig. 2) at any instant, in centimes, per candle-hour; obtained by taking the ratio of the ordinates of curves C and D.

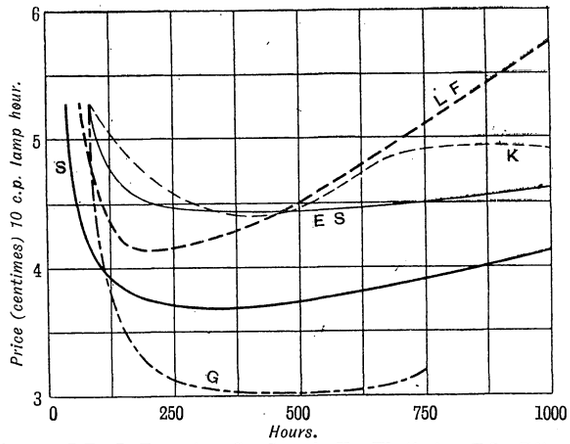
$$\text{Specific cost} = \frac{\text{Total cost in francs}}{\text{Quantity of light in candle-hours.}}$$



S.—Siemens. L.F.—La Française. G.—Gerard. K.—Khotinsky. E.S.—Edison-Swan.

FIG. 1.—Candle-power as a function of Time.

This last curve characterises every type of lamp working in a given manner. It shows, generally speaking that, during the first hours the specific cost, asymptotic to the axis of y, rapidly diminishes, then falls more slowly to a minimum, and then ascends indefinitely owing to the reduction of the candle-power. There is, therefore, a moment at which a given quantity of light has been obtained for a minimum price. It is precisely at that moment that we must remove the lamp, replace it, and break it; or, rather, return it to the maker, and obtain a sum varying from 5 to 15 centimes, say, on the average, 10 centimes.



S.—Siemens. L.F.—La Française. G.—Gerard. K.—Khotinsky. E.S.—Edison-Swan

FIG. 2.—*Specific Cost* as a function of Time.

Mr. O'Keenan's method, applied to 102 volts 16 c.p. lamps of La Compagnie la Française, shows that the *smashing point* for them arrives after 200 hours' use. In fact, if we keep them burning after that the result is that, after 2,000 hours, we have a 5 c.p. lamp taking 8·8 watts to the candle. Mr. O'Keenan has in his possession a curiosity in the shape of an old, much-blackened lamp, taking 17 watts to the candle. That figure alone shows that the lamp deserves to have been broken long ago. In no case (*see* Fig. 2) is the *smashing point* deferred beyond 500 hours.

The conclusion which stands out clearly, after a study of all these curves, is that the *smashing point* being always reached *before* the nominal life of the lamp has been spanned, our lamps last too long. To remedy this defect the mode of manufacture and the standardising should be modified, so as to make the smashing point coincide with the life; in other words, the

Hosted by Google

lamp must be *pushed*. This is shown by the curves which have been obtained when working at 102 to 110 volts in lamps of the same make and type.

Until this consummation is reached the consumer will continue to demand long-lived lamps, and it will be very difficult to make him understand that it is to his interest to break a lamp after a few hundred hours' use, because the advantage will not present itself to him in the guise of a material and direct economy. The substitution of an old lamp for a new one does not sensibly modify the indications of the meter, and the substitution is itself an undoubted expense; to wit, the cost of the new lamp. The gain, of course, lies in obtaining more light, or, to speak more accurately, in obtaining a larger quantity of light for the same price. But this is a form of economy which scarcely appeals to the generality of consumers. For a long time to come the long life of incandescent lamps will continue to be misused without people seeing, as in the case of all other abuses, the error of their ways.

THE SWINBURNE ELECTROSTATIC WATT OR VOLTMETER.

This instrument, of which we have recently heard so much, has been greatly improved since the first original ones were supplied to Dr. Fleming for his transformer tests. In its present form the instrument is a very delicate and accurate instrument.

The electro-magnetic damping arrangement has been done away with, and an adjustable oil-damper substituted, which enables any degree of damping desired to be obtained. The moving system has been very much lightened, and so the troubles of creeping zero, &c., have been eliminated. The torsion head has been improved by adding a tangent screw fine adjustment, to enable the spot to be brought accurately to zero, but the first rough adjustment may be done by turning the head as usual. A vernier has also been added to the scale, so that the pointer may be read to one-tenth of a degree. On steady volts the new instrument may be read to half a volt in 2,000 volts.

Dr. Fleming's initial difficulty with cross sparking was simply due to his using for 1,800 and 2,000 volts, instruments which had only been designed and intended for 1,000. Messrs. Swinburne have, however, increased the distance between the vanes and boxes considerably, so that there is now no danger of sparking with high volts.

IMPROVEMENTS IN ELECTRIC MAINS AND DISTRIBURION.

At the Manchester meeting of the British Association in 1887 Prof. G. Forbes proposed to construct mains for electrical distribution in the form of copper tubes. The stiffness of such a conductor presents advantages, and they can be easily drawn from flat strip. A gap or slot of a quarter of an inch was to be left between the edges of the strip, and it was proposed that as the load increased owing to the requirements of the district, a number of bare copper wires could be drawn through from manhole to manhole. Connection between the lengths of the conductors was not fully worked out, and junction boxes were ignored, house connections were to be made through 1in. holes into which gas pipes were to be tapped. This was put forward as an essentially "bare copper" system, and insulating discs of porcelain were to support the copper tubes in cast-iron pipes. Nothing more has been heard of copper tubes, and without discussing who was the actual inventor, it is safe to say that Mr. Crompton has since fully developed with complete success the strip and conduit system, and that others have followed, not always with equal success. To meet the difficulties of entrance of water into badly-made, ill-drained, or leaky conduits, and to save the trouble of tightening, Messrs. Gordon and Co. propose to adopt brazed copper tubes in porcelain ring insulators, and to lay these on a concrete bed at the bottom of a trench, and run them in solid with an asphalte composition. It is proposed to use tubes from three-quarters of an inch in external diameter, one-eighth of an inch thick, to 2 inches diameter, and one-sixteenth of an inch thick. It is suggested that pilot wires or telephone wires may be laid in the tubes, and Prof. Forbes' idea of reinforcing the section of the conductor by drawing in bare copper strand is also contemplated.

In the absence of any information about the asphalte composition, we are not surprised to hear that the insulation resistance is not quite so high as that of the best cables, but the claim that it is practically impossible to injure it must be received with caution. We are informed that in the course of the experimental test a piece of wet clay fell upon the asphalte before it was set and gradually sunk through it and formed a connection across the tubes. The insulation resistance at once fell very considerably, though not sufficiently to stop the use of the mains. Bubbles appeared for about three-quarters of an hour over the point where the clay had sunk in, and at the end of that period the insulation resistance rose to its full amount, and the main appeared to be in perfect order. On removing the clay afterwards it was found to be baked hard and dry. A sheet of calico is to be laid over the asphalte to prevent such accidents in future. It is intended to use this system at present solely for circuits not exceeding 200 volts, but an experimental length of it at Bray has been subjected continuously to 1,000 volts, and remains in perfect order.

Messrs. Gordon and Co. claim that in case of any fault occurring, "a little heat is developed at the fault which at once melts the asphaltes in the neighbourhood; but it then flows in and repairs the fault." We hope that this excellent result may be realised in practice. The stiffness of the tubes is a good point, and certain readily calculable advantages may be realised by the decrease in virtual resistance for alternating currents. We are not informed how joints are made; these become of some importance when the short lengths of tube and the long lengths of strip are considered. Attempts to secure stiffness by placing copper strip on edge have been made by several contractors who followed Mr. Crompton's plan at a respectful distance, but he had tried it and had abandoned it before the strained flat strip was arrived at. The use of tubes, however, suggests that strip might be rolled into a V like angle iron. This would hardly span eleven or twelve yards like the strained strips, but would offer facilities for drawing in additional length, and if more convenient, the veeing could be done on the spot, the strip being brought on to the work in the flat. The virtual resistance of such "angle copper" would be much more nearly that of a thin tube than of a solid rod.

Messrs. Gordon and Co. are also introducing improvements in alternate-current distribution which are intended to avoid the royalties demanded for the three-wire system. In order to avoid committing contempt of Court, we hasten to add that by this invention the third wire is dispensed with altogether. The alternating current is to be supplied at 200 volts, from sub-stations to feeding points. Here an equalising transformer is placed, which is wound with two circuits of a similar number of turns. These two circuits are connected in series across the 200-volt mains, and 100-volt service wires are led from each. When the load on each circuit is the same, the transformer is inoperative, but when the loads differ, the balance is transformed and transferred from the lighter to the more heavily-loaded side. So many minds have been busy with transformers and methods of using them, that it seems difficult to find any arrangement which has not already been suggested, but if this invention is found to be both novel and practically efficient, it ought to be of considerable value. An interesting feature of this arrangement is that this transformer is the exact analogue (using this term in its strict biological sense) to the batteries used at the stations of the Kensington Knightsbridge Company. We understand that both the improvements in the mains and this method of distribution have been devised by Mr. T. Tomlinson, who is the inventor of the very ingenious automatic sub-station regulator which has been described in these columns.

LEGAL INTELLIGENCE.

Hopkinson v. The St. James's and Pall Mall Electric Lighting Company (Limited).

THURSDAY, NOVEMBER 24TH.

On the hearing of this case being resumed, Mr. RANKIN KENNEDY was re-called and further cross-examined by Sir HORACE DAVEY, and stated that in the early part of 1882 he was engaged in perfecting the Kennedy arc lamp. He was sure that he went regularly to the workshop before he went to the Crystal Palace. It was not the fact that he used to conduct his business at Mr. Muir's office round the corner. Before he went to tho Crystal Palace there was no regular incandescent lighting though he had seen one or two Maxim lamps there lighted occasionally. The lamps were placed on the circuit of Siemen's dynamo. He did not closely examine the way the lamps were attached to the wires. He could not therefore tell whether some of the lamps were attached to the first and second wire, and some to the second and third. He would pledge his word that there were never more than two wires attached to the dynamo.

Examined with regard to diagram J.D. A.1 (see *The Electrician*, November 11, p. 47), witness said that it was generally correct. Although Mr. Andrews says he personally connected a third wire with the dynamo, witness felt sufficiently positive on the point to contradict Mr. Andrews. Mr. Andrews was head of the workshop and witness's visits to the workshop were intermittent. Occasionally he went there not upon any business connected with the Maxim lamps, but on business connected with the Kennedy lamp which was preparing for the Crystal Palace. He must necessarily have seen the third wire if it had been hanging from the roof. He had altered the Siemens' dynamo some time in June. The centre ring, which had been previously disconnected, was re-connected by him. The third ring was never removed. It was merely disconnected. No alteration had been made in the construction of the dynamo, but merely in the connections, and they could be made good in, say, half an hour. When he took the dynamo in hand the broad ring formed one pole, say the negative pole. The other two rings were positive to the broad ring. Before he took it in hand and re-connected the broad ring it was working all coils in series with the two narrow rings forming the two poles.

Re-examined by Mr. ASTON, witness stated that during the period before he went to the Crystal Palace, he constantly went to the workshop for the experimental purposes referred to, and ascertained the construction of the dynamo, as he wanted to understand the construction of that particular dynamo, dynamo making being his particular study at that date, and that being the first Siemens' alternating machine he had had an opportunity of actually having in hand. He returned from the Crystal Palace on the 19th May, and went to the workshop oftener than ever. They were busy preparing six arc lamps to go to Chatham Dockyard. The dynamo and engine were entirely idle at the time. No incandescent lamps were being made and no lighting was required. They never made any that were fit even to be tested. When he returned from the Crystal Palace and examined the dynamo, it was not in a condition to be used in connection with the three-wire system. He saw it with the middle ring disconnected both before he went to the Crystal Palace and after. During the whole of the time that he was there, both before the Crystal Palace and after, there were only two wires which came down from the roof and were connected with the dynamo. But supposing that a third wire came from the roof in the same way as the other two wires, it could not have been done so without his observing it.

Mr. DAVID GRAHAM, examined by Mr. HOPKINSON, stated that at the close of the year 1881 he was in business and very much interested in electrical matters. He became acquainted with Mr. Rankin Kennedy in October, 1881. The Otto gas engine was 2 H.P. He remembered taking the premises at Sauchiehall-lane on a weekly tenancy. He remembered the formation of the National Electric Company at the beginning of the year 1882. He was Managing Director of the Company. He knew what the three-wire system was now, but not then. He never saw anything of the sort. Mr. Andrews never told him anything of the kind. Mr. Andrews was then entirely a servant of the Company, and employed to assist in the experiments that were going on, working under witness. They never produced an incandescent lamp fit to be sold. The glass blowing went on at Sauchiehall-lane, but previously it went on in his premises adjoining. In his view it was a perfectly private workshop. It was on the second floor and entered from a back lane, and up a back stair. It certainly was not a place where he expected people to come in without his permission. With regard to the practical lighting of the place, till he went away on the 1st April, it was gas lighting. He never saw any system of electrical lighting there. Arc lighting was the only lighting that he saw, and that was experimental or testing the lamps that were being made.

Cross-examined by Sir HORACE DAVEY, witness stated that from April to June he had no personal knowledge of what was being done at the workshop.

Re-examined by Mr. ASTON, witness stated that he went away to the Crystal Palace from about April to May. During that time he had constant reports from Glasgow. He never heard of any use of the three-wire system by Mr. Andrews or anybody else. He never heard of it until this case was brought up.

Mr. DAVID JOHNSTON SMITH, examined by Mr. HOPKINSON, stated that he was the Secretary of the National Electrical Company in the year 1882. There was nothing successfully manufactured there and sold. The workshop was a private workshop.

Cross-examined by Sir HORACE DAVEY, witness stated that he never had occasion himself to refuse anybody admission, and he was not personally aware of anybody being refused who requested to see what was going on.

Mr. WILLIAM MACFARLANE, examined by Mr. ASTON, stated that early in 1882 he was engaged at the Sauchiehall-lane Works, Glasgow. He was there until the beginning of July in the same year. The Siemens' dynamo was there when he went there in March. He did not examine it. He was particularly engaged on Mr. Kennedy's lamps. During the time he was there the workshop was not lighted with incandescent lamps. He remembered the wires which came down from the ceiling and were connected with the dynamo. There were two. The workshop was lighted all the time that he was there by gas. His communications with Mr. Andrews were personal and direct and constant. He remembered once seeing two of Andrews' plate lamps tried at the same time. He remembered the pranks played by the workmen with the wires that went from the dynamo. He had seen them short-circuit the wires. The result of the short-circuiting was that one went out whilst the other blazed up. Being unable to form a distinct arc it blazed up and made a hissing sound.

Cross-examined by Sir HORACE DAVEY, witness stated that in 1882 he was an instrument maker in the workshop. He was not engaged on testing or any of the electrical part of the business, but on making Kennedy's lamps, and Mr. Andrews' lamps. He never saw any Maxim lamps placed upon the wires in the workshop. All the lamps that he saw burning he understood to be Akaster—purely experimental.

Sir HORACE DAVEY: You did not see any Maxim lamps put upon the wires?—Not for lighting the shop.

Not in the shop?—No, not for lighting up the shop.

Will you be good enough to answer my question. Did you or did you not see any Maxim lamps put upon the wires?

Mr. JUSTICE ROMER: At all; for any purpose?—Well, I have no knowledge of that, because we were not allowed to go where Mr. Andrews carried on his experiments with those lamps among the racks, and, therefore, I could not say what wires were on.

Sir HORACE DAVEY: Did you or did you not see lamps placed upon the wires you have mentioned and burning?—I have seen lamps put on the wires.

Incandescent lamps?—Incandescent lamps.

And burning?—And burning.

And giving light?—Yes.

In this workshop?—In this workshop, but not for the purpose of lighting.

Continuing, WITNESS stated that some of the lamps burnt almost a day, sometimes only a very short time, according to what Mr. Andrews was wanting. After Mr. Andrews went away he had been there till twelve o'clock at night and worked by gaslight.

Sir HORACE DAVEY: Did you ever see the incandescent lamps burning at night for the purpose of giving light?—No.

Did you see the incandescent lamps being made?—Yes, I have seen them on the racks.

Did you observe, or did you not observe, whether those racks were placed on three wires, or two wires, or how many wires they were placed on?—Two wires in all that ever I saw.

Are you prepared to say that there were not three wires hung round the room upon which the lamps were placed?—Well, I never saw them.

Mr. JAMES CURRIE, examined by Mr. HOPKINSON, stated that he was a glass blower. About the end of March, 1882, he went to the Sauchiehall-lane workshop, and was engaged by Mr. Graham. He stayed from the end of March to the end of April. His duty there was blowing lamp bulbs. While he was there the place was lighted with gas. He had seen one Maxim lamp in the workshop, on the wires running round the side of the workshop. He did not know what it was there for.

Mr. HENRY ELGIN, examined by Mr. HOPKINSON, stated that he was a clerk in the employ of Messrs. Crossley Bros., Openshaw, near Manchester. A 2-horse gas engine was ordered, supplied, and paid for.

Cross-examined by Sir HORACE DAVEY, witness stated that it was 2 H.P. nominal.

Mr. ROBERT WILSON, examined by Mr. HOPKINSON, stated that he was the London manager of Messrs. Crossley Bros. The capacity of their 2 H.P. nominal engines was from 24 to 28 lamps, assuming 16 c.p lamps. He had no experience with Maxim lamps.

Dr. JAMES THOMSON BOTTOMLEY was then examined by Mr. MOULTON. At the end of 1881 he was asked by Mr. Graham personally to come and assist at the lighting of the Fine Art Gallery. Mr. Graham was in a difficulty, and applied to witness to assist him. Neither at the Fine Art Gallery nor in the workshop at Sauchiehall-lane did he ever see an arrangement wherein a third main was taken back to the middle point between the two coils in series. The three-wire system was a novelty to him when he heard of Dr. Hopkinson's discovery.

Mr. MOULTON: Is the model S.P.T. 4 made in accordance with the direction of the specification?—Yes, I believe it is. I may say that I have not very intimately studied the specification. It has not been put before me.

Now will that work on an alternating system where not the whole, but only a portion, of the current passes through the thick coil?—Yes, this will work. I have seen it work.

In continuation, witness stated that with regard to the defendants' model (J.S.1), he should expect it to have the largest mutual induction; the disturbing element when the regulator was applied to alternating currents. He should expect one made according to Fig. 2 to work better than one made like J.S.1 on account of the arrangement of the coils. From his experiments with S.P.T. 4 he believed such an instrument would do the work that the patentee wanted it to do perfectly.

Cross-examined by Sir HORACE DAVEY, witness stated that he did not see the experiments which had been conducted the previous night.

Re-examined by Mr. MOULTON, witness stated that when they short-circuited the coil they exaggerated the mutual induction currents. There-

Hosted by Google

fore, if mutual induction currents were sufficient to smother the action of the instrument, it would have been smothered. But it acted as a voltmeter perfectly.

Dr. JOHN HOPKINSON was recalled and further examined by Mr. MOULTON, and stated he was present the previous night when the experiments were being made with the working model S.P.T. 4. The total drop at the lamps when the complete current was on was 10 per cent. of the voltage. The lamps were working at about 50 volts, and the drop was 10 per cent., and, therefore, about 5 volts from one end of the conductor to the other. The action of the indicator would correspond to its action on an actual system.

Further cross-examined by Sir HORACE DAVEY, witness stated that the experiment was not arranged with such a relatively high resistance that the self-induction could not have any effect. He denied that in order to get sufficient main resistance to shunt with the coil of the regulator they would have to go outside the station.

Re-examined by Mr. MOULTON, witness stated that the model was not altered at all, the only current available was about 25 amperes. To change that to a working current of an installation on a large scale, they would have to change the 25 amperes to thousands of amperes.

Lord KELVIN, recalled and further examined by Mr. ASTON, stated that at the date of Dr. Hopkinson's patent the system of lighting by utilisation of three wires was, in his opinion, a novelty. He was not shown anything at the workshop at Sauchiehall-lane like the three-wire system of Dr. Hopkinson's. Looking at the two models (J.S.1 and S.P.T.4) before him, witness stated that S.P.T.4 corresponded absolutely with what he found in Dr. Hopkinson's, Fig. 2. The other one differed from the drawing in having the thick coil *outside* the thin coil. That was a material difference. It would largely increase the mutual induction between the two coils. He had that morning seen S.P.T.4 tried. He could now undertake to place it on any installation for public lighting, however large, and to make it work within a close percentage. He had not the slightest doubt that the apparatus as shown in Fig. 2 was a useful invention, and it was sufficiently described in the specification to enable it to be usefully worked with alternating and with continuous currents.

Cross-examined by Sir HORACE DAVEY, witness stated that he was not personally aware of any case in which the regulator had been put in practical operation. The resistance of the main and the wire which went round in the experiment was practically $\frac{1}{3\,6}$th and $\frac{1}{3\,0\,0}$th of an ohm respectively.

Mr. GEORGE BICKHAM DUNN, examined by Mr. HOPKINSON, said that he was in charge of the generating station at Sardinia-street, and gave evidence with regard to the "compensators" supplied by the Westinghouse Electric Company.

Cross-examined by Sir HORACE DAVEY, witness stated that they did not use the compensators now.

Mr. HOPKINSON: Because he does not want them!

Sir HORACE DAVEY: You do not use these compensators as you call them?—No, we do not use them.

Did you ever use them?—No, we never used them.

Do you use pilot wires?—No we do not.

Mr. JAMES SWINBURNE, recalled and further examined by Sir HORACE DAVEY, described what happend at the Westinghouse office the previous day in the presence of Mr. Harrison, Mr. Mordey, Dr. Hopkinson, Mr. Moulton, Mr. Alfred Hopkinson, Mr. Belfield, Mr. Hayward, and Mr. Owen, and one or two others. He saw the instrument coupled up on a temporary installation of lamps. There was a wire of platinum or high-resistance material put to represent the feeder. The fine wire was connected in the right way to the dynamo. He tested the working of the instrument, and under those circumstances he considered it worked well. The portion of the main was about ten times the resistance of the circuit which went round the coil, perhaps less; eight and a-half was what was suggested. The effect of increasing the resistance was to overcome the error due to self-induction. Supposing that the model installation had been converted into actual practice, preserving the same relative scale in every respect, it would not be a practical thing, because it involved taking the connections down about a third of a mile and adjusting them.

Cross-examined by Mr. MOULTON, witness stated that he could have told them that before if they had put the experiment to him in the witness-box the day before. He could have told them at once that the instrument might work under those circumstance, but that it would not work under practical circumstances.

Mr. ASTON: If your Lordship pleases that will be the plaintiff's case.

Mr. JUSTICE ROMER: Now we have all the evidence in.

Mr. MOULTON: We have.

Sir HORACE DAVEY: I think we have now.

Sir HORACE DAVEY, Q.C., in summing up the case for the defendants, said the case was an extremely simple one; it was merely the construction of a document. The question really was whether Dr. Hopkinson's specification was so framed as to comprise the case of a third wire used with lamps arranged in series, as well as in parallel, say two arc lights or two electromoters. If so, then it was admitted by Dr. Hopkinson that it was anticipated by the Inchicore arrangement, and his side said also by that used at the Alexandra Palace. If their construction was right then the invention was anticipated, or there was really no patentable invention in using incandescent lamps instead of arc, or "devices for consuming electricity," or in adding an additional number of bridges to the one already used. These two propositions were different—(1) The true construction of the specification comprised two arrangements, parallel as well as series. (2) Assuming this was wrong, then came the question whether a man could have a patent merely for substituting one lamp for another? But if the specification excluded all but incandescent lamps and any electrical appliance save when arranged in parallel, and the Court should think it was "subject matter" to extend the use of the third wire from arcs in series to incandescent lamps in parallel, then the patent would be valid. The first and primary question was then one of construction. Sir Richard Webster, in cross-examination of Prof. Silvanus Thompson, asked him if there was anything in the specification to lead a workman to use the third wire with two arcs or motors. An ingenious question adroitly put, but not the point. The real question was not whether there was anything *pointing* to the use of series, or motors, or other appliances, but whether the description did or did not *include* these things. The question was, whether the patentee's claim was couched in such language as to include these things. To say that the patentee had in his mind electric lighting by incandescent lamps in parallel did not answer the question. Had he not drawn his description to include other uses, and drafted his claim in such well-chosen terms as to cover other uses of his invention, such that installations like those at the Alexandra Palace and Inchicore would be an infringement had they been put up after and not before the date of the patent? That was the real question, and not the one put to Dr. Thompson. His question of construction was for the Court only. Experts' evidence was wholly irrelevant, and only given to throw dust in one's eyes. He protested against the doctrine that if an invention was not useful for a particular kind of installation that, therefore, such particular application of it was not within the patent. It was said that the three-wire system was of no use in series arc lighting, or arrangements other than parallel. The true conclusion from this premiss was not that series, &c., were excluded, but that if the specification properly construed applied to these cases, then the patent was valid. Or, to put it another way, they must *first* construe the specification before they considered the evidence whether a particular application of the invention were useful or not. He would now consider the specification more in detail, and in doing so note the way the case was opened. They were told by Sir R. Webster that the specification was confined to incandescent lighting. No more would be heard of that argument for three reasons: (1) Dr. Hopkinson admitted in the box that an electricity consuming appliance might be substituted for incandescent lamps; (2) he also told them it was to be applied to all kinds of uses; and (3) there was not a word in the specification so confining it. That was the way the other side presented their case. Would they adhere to it in reply? It was necessary to take the words of the specification in their natural meaning. What was the argument his opponents used as to the construction of the specification? They said that the first invention was for a regulator for working arrangements at a fixed potential, and that such was only required when they had an arrangement of incandescent lamps in parallel. He might admit that much, that the regulator was only useful when a fixed potential was required, and therefore only useful in such a case as parallel incandescent lighting. His opponents then went on to say, because it was applicable only when one wanted a fixed potential, and one wanted it only in this case of parallel lighting, therefore, people were to infer that the patentee confined the second invention also to where the potential was to be fixed, although when he described his invention he said nothing about confining it to parallel arrangements. It was the most fallacious argument that he ever heard. One might insert the words "at a fixed potential" in the second line of the specification, immediately after the word "maintaining," and read it, "maintaining at a fixed potential the electromotive force in a system of conductors for an electric supply;" otherwise "maintaining" had no meaning. The object of the regulator was to "keep the E.M.F. at a fixed potential," not merely to "keep it." Hence, "such conductors" meant simply conductors for electric supply, and not as the other side said, conductors for delivering electricity at a fixed potential. A little further down, in the disclaimed portion, patentee spoke of measuring the quantity of electricity drawn from "the system of conductors." Next he spoke of the necessity of keeping the potential at the delivery end constant, varying it when necessary at the generator. The words were all used there in the same way, not a word to confine it to a parallel system. He considered further down the economising of cost of conductors, and spoke of placing "*two* systems of lamps or other appliances consuming electricity of approximately equal capacity also in series." That was, one might use two arc lamps, say, in series, so that they could put one out; there was not a word there about either fixed potential or parallel arrangement. Take the case of two "electricity consuming appliances," say, motors—one was required to work at 9 H.P. and the other at 1 H.P. Here the third wire would convey the excess of current, so that the 1 H.P. machine was not "choked." Patentee next described the method of joining the wire between the two systems of appliances and the two dynamos. Suppose two arc lamps were put on Although both might be of the same capacity originally, yet, as a matter of fact, they would vary from time to time, and, therefore, a slightly different current would be required. The third wire conveyed that difference from or to the dynamo, as the case might be. They had the evidence in Prof. Thompson's illustration of the motors of approximately equal capacity, where he said the excess or deficiency would pass down the central wire. Mr. Swinburne and Prof. Kennedy gave evidence to the same effect. Take the case of the Alexandra Palace installation with Mr. Crompton's lamps. One could not be put out without putting both out, the third wire enabled this to be done. Similarly they could have six—three on each side; then three could be extinguished, and the other three left. Prof. Thompson's evidence on the sixth day of the trial was to the same effect. He spoke of the advantages of the new system. Three wires instead of four; again, they saved energy; people were familiar with the case of this in arc lamps, the third wire would have same effect if one of the lamps got more current than it ought to, it would convey the difference. Dr. Hopkinson on the second day said the same thing, only he thought it would not be useful; he said that the variation in the resistance of the lamps would be injurious, as it would make the lights unequal, the *operation* of the third wire to obviate this result would be the same as in his arrangement. Mr. Crompton's actual experience (spoken to on the fifth day) showed the same thing. Unless the central wire were used both lamps would go out when the "feeding" mechanism operated in one only.

Hosted by Google

Lord Kelvin admitted that the Alexandra Palace installation was Dr. Hopkinson's three-wire system applied to two arc lamps. Mr. Swinburne's evidence as to the Inchicore installation was precisely to the same effect. In order to justify the construction contended for by the other side, they must say that the case of a *single* consuming appliance on each side of the middle wire was excluded There was nothing in the description to confine it to incandescent lamps or parallel arrangement. No doubt the patentee contemplated such, but he had not confined his specification to them. If he confined it to *several* series placed in parallel, why did he not say so? The fact that in one arrangement one derived more advantages from it than in another, was no ground for saying that the patentee meant to confine his invention to such arrangements. The same criticism applied to his description of Fig. 5. Not a word there confining it to a parallel arrangement. Nothing was said about the number of series. Where was the line to be drawn, at 3 or 2? If so, why? Where was the series excluded? He (Sir Horace Davey) had nothing to say to the "spirit of the specification," but must look at the words only. It was the same thing in principle whether applied to one series or one hundred. Undoubtedly the advantages were more and wider in the case of many lamps than of two as in the Alexandra Palace installation. But in that humble case there were still advantages derived from the invention.

At this stage the Court adjourned.

FRIDAY, NOVEMBER 25TH.

On the hearing of the case being resumed, Sir HORACE DAVEY continued his speech:—They now came, he said, to the consideration of the claims. The patentee here, in his second claim, spoke of a system of electrical distribution or *supply*." He (Sir Horace) would seek the essential features which the patentee emphasised—"the employment of three (or more) conductors in combination with two (or more) dynamo machines in series substantially as hereinbefore *described with reference* to Fig. 5 of the accompanying drawings," &c. Patentee did not say described in Fig. 5, but "with reference to" Fig. 5, that was by the letterpress which was *illustrated* by certain diagrams and drawings. It was to the letterpress, and not the diagrams, they must look. All that he really had claimed was a series of two or more electricity consuming appliances arranged in series and connected to two dynamos also in series by a third wire from a point between the appliances to a point between the dynamos. It was not the distinction between parallel and series, but between one series or more. The invention could not be confined to incandescent lighting because the patentee had himself extended it to others, nor could it be confined to more series than one, because the letterpress only spoke of one. The view taken by defendants was strongly supported by Prof. Kennedy's evidence, on which there was no cross-examination. Prof. Kennedy explained in the box fully how the advantages mentioned by the patentee were gained when his system was applied to a single series of two arc lamps. His figures as to saving of energy were uncontradicted. He was supported by the evidence of Mr. Lauckert, who made the dynamos which had been described. Mr. Lauckert's figures were also undisputed. He described the advantages gained in "the City of Berlin." His evidence proved two things—(1) actual saving of energy and therefore of coal and money, and (2) that there was really no invention in adding on any number of series when they were given one series of two lamps. As to the Alexandra Palace and Inchicore installations—the plaintiffs had ample notice and no evidence had been called to question their existence—they were not in dispute. Nor was it disputed that they were anticipations of the defendants' construction if the specification was the right one. Then, on the question of subject matter, Sir Frederick Bramwell said any electrician would have known in 1882 how to substitute one system, say a collection of multiple bridges for another, say, arc lamps. Use of third wire was known with two arcs in series. Could there be any patentable invention in merely multiplying the number of series? A word as to the last anticipation. Mr. Andrews' memory could be relied on for every detail, but his evidence went to prove that no invention was needed to change from a known arrangement to that described by the patentee. The dynamo was similar to that used at Inchicore—had the third collector ring. Mr. Andrews never thought there was any difficulty in arranging it for incandescent lamps in multiple parallel bridge. Mr. Rankin Kennedy's evidence supported the defendants' case. He said the construction of the dynamo was as described by Mr. Lauckert, and that there were three wires round the room. He differed from the defendants' witnesses when he said that the third wire was disconnected from the dynamo. Mr. Andrews was positive on that point, and he was in a better position to know. He was also a most disinterested witness, having no interest whatever in the case. His *bonâ fides* could not be doubted, but memory might be fallible. So, too, was Mr. Rankin Kennedy's. But the latter was there for a different purpose, and his attention was not called to the dynamo particularly. The other witnesses supported the defendants' view. The user was as open to the public as his (Sir Horace Davey's) house to his guests. If his guests saw an invention, would not that be publication? *Humpherson* v. *Syer* was the authority. As to the utility of the regulator, it had never been used. His witnesses had proved that it would not work with alternating currents. The other side had made their own experiment, choosing their own conditions, and had shown, according to Mr. Swinburne's evidence, that to translate their experiment to a working system would not produce a practicable machine. Nor was there in the specification any directions to the workmen to couple two alternating dynamos rigidly, which was admittedly necessary.

Mr. MOULTON, Q.C., then reviewed the evidence on behalf of Dr. Hopkinson. On the first claim, said Mr. Moulton, the only point made was that it was not useful, *i.e.*, would not work with alternating currents. This was not so. That form of regulator in which all the current went through the thick wire would work in all cases. The objection, then, only came to this, that they might if they tried a particular form, and one unsuitable find that it would not work. What were the facts? Dr. Hopkinson invented and constructed a machine which, by falsifying the record of pressure at the dynamo by a proper amount, would enable one directly to observe the pressure at the delivery end of the main where constancy was essential. It was very ingenious and useful. Lord Kelvin described it as a very useful instrument, and Mr. Belfield testified to its being used in a modified form throughout the United States. There was no serious attack on the utility of the instrument, except in the one case of alternating currents, where the whole current was not passed through it. It was no objection to say it had not actually been used, *e.g.*, the case of the vacuum brake, 1878, when it was proved that the whole thing had been fully described in 1851 and never used for 22 years. Even if the patentee thought it more widely useful than it really was, still he had not failed in his duty, made no false suggestion, but simply over-estimated some of its powers. Compare the case of an injector. Could it be said to be devoid of utility because it could be put into a boiler of such a construction as not to be of any use in that particular case? There was the direct evidence of Lord Kelvin, who said now that he had made experiments he had no doubt he could make it work on any system. The conditions of experiment, which his opponents made so much of, had nothing to say to the result. Of course, conditions in a laboratory were not those of outside work, but it was all the same if no modifications were made which interfered with testing the essential principles of the instrument. Lord Kelvin was a master of the method of scientific experiment. He (Mr. Moulton) relied on his experience and conclusions. The weight of evidence called by plaintiffs established the fact that the regulator would succeed. As to the attack on the second claim, he would take the minor point first, namely, the objection to the sufficiency of the specification. The other side said that it was insufficient, because if they took the case of alternating-current dynamos there were no directions that the dynamos must be rigidly coupled, and that in 1882 such directions were necessary to enable one to work two dynamos in series. Lord Kelvin said that a workman would see the necessity for it as soon as he fitted up the machine. As to his friends' law, they joined issue at once. The patent was one for setting up electrical machinery, and the specification was, therefore, directed to the engineer who planned the machinery. It was necessary for the other side to show that electrical engineers who designed plant and machinery required instruction on such a point. Witnesses naturally got a bias from having been occupied in looking at a case from the point of view of one side only; their judgment, in spite of themselves, became warped. The aniline dye case decided that specifications were to be read as addressed to that class of men who would be employed to carry out such work as described. If they put two dynamos in series to work at, say, 100 volts each, it was well known that the waves of current must keep time in the two machines. Hence the question was one purely for the mechanician to solve. Wilde pointed out an exception to this rule, namely, when they worked in parallel. All the witnesses said that the rigid coupling was an easy thing to do. He now came to the main point of the case, the second objection to the second claim, viz., want of novelty and subject matter. The main question was undoubtedly the construction of the specification. As to this Sir Horace Davey has attacked them for "torturing the English language." Now, all Sir Horace Davey's witnesses said that what they believed the patentee had in his mind was a parallel system of supply. No electrician was called who said otherwise. Now, in considering canons of construction, one must bear in mind that in most cases, although not in this, specifications were drawn by comparatively unlearned persons. It had always been held both for and against a patentee that they must consider what it was he had in his mind. Now that it was admitted by the defendants' witnesses that it was a parallel system of distribution the patentee had in his mind—that was, that he was confining himself to a parallel system—they must bear that in mind when putting a construction on doubtful points or expressions. Sir Horace Davey's contention was suited to the days of special demurrers, when he would have distinguished himself as much as he has done now.

Mr. JUSTICE ROMER: You must not think now of the anticipations.

Mr. MOULTON: His notion was that they must not assume that all these alleged anticipations were present to the mind of the patentee when drafting his specification. One started with the general knowledge of the time. One was entitled to find out the interpretation of terms of art, and to consider the electrical knowledge in the "background" of the mind of the patentee.

Mr. JUSTICE ROMER: Your difficulty is this—what did he confine himself to? The patentee has not referred to a parallel system!

Mr. MOULTON: The defendants said, Why did he not expressly refer to parallel? The plaintiffs said he *did*. Sir Horace Davey failed to appreciate the evidence of Mr. Swinburne on this point. He said that electricians knew what an "electric supply at a fixed potential" was. He (Mr. Moulton) said that phase was a term of art, and one well known in 1882, and meant supplied at a fixed pressure where the consumer took it. Mr. Swinburne admitted it was a well-known phrase. It was a far more accurate one than "parallel distribution."

Mr. JUSTICE ROMER: If so, what does maintaining refer to?

Mr. MOULTON: The E.M.F., which was synonymous with "potential." If they substituted for "an electric supply at a fixed potential" the words arranged in parallel, the meaning was quite clear and reasonable. It was a most accurate description. "Parallel system" would not do. It would not include a case of two lights. The real test was whether each consumer was to be supplied with electricity at a fixed potential. Dr. Hopkinson chose the more accurate differentia instead of the looser and more popular expression; he used the best electrical language. They dared not suggest it meant anything else. In a series system consumers could not have electricity at a fixed potential, it must vary throughout the series. No amount of "torturing" could make those words mean anything else. This was borne out by the word "such," in line 3. It was no objection to say it

Hosted by Google

might mean something else, and hence it *did*. The references to "delivery" and "distribution" were consistent only with a parallel system. So, too, the reference to the meter. That would be absurd in a series system, as the same current went to each consumer, and must do so. In line 25, page 3, patentee referred to "service mains." He could not have used a term more indicative of the parallel system. In series there were no "branches." Again, in line 31, the patentee used "mains" as opposed to branches. Hence, they must have a parallel system. It was never suggested that this language was not suited to a parallel system. Prof. Silvanus Thompson said there was no reference whatever to direct one to apply it to a series system. Here the writer was a competent electrician, writing for electricians; all references were to parallel, and none referred to series only. The cable at the Alexandra Palace would be continuous. No electrician would ever have dreamt of "branches" in such a connection. In the three-wire system there was no saving on the branch conductors. They saw here the accuracy of the mind of the writer, not all conductors, but "main" only. Again, for commercial supply, meters were needed. He never mentioned any special system, it never entered his head to do so. Quantity varied in parallel system; in the series quantity must be maintained constant, and potential varied to suit consumption. The meters were only needed in the parallel system. The switching out or in of dynamo referred to in the disclaimed portion referred to parallel only. "Standard amount" of potential was meaningless when applied to series. "Network" could not refer to series. Page 5 evidently referred to parallel. [The learned counsel read and commented on many expressions in support of this view.] "System" did not mean a single case; *see* "Webster's Dictionary." "Distribution or supply" meant to many, not merely a single circuit. When the patentee said "substantially as hereinbefore described," "with reference to Fig. 5," he referred to letterpress, and as he (Mr. Moulton) had shown, the letterpress implied referred to a parallel system only. The concluding words, "as set forth," placed it beyond all doubt. The patentee had now no longer an interest in the patent. Writing as an electrician, his specification applied to parallel systems only.

At this stage the Court adjourned.

MONDAY, NOVEMBER 28TH.

On the hearing of this action being resumed on Monday, Mr. MOULTON, Q.C., continued his speech. What did the words "consistent with efficiency and safety" mean? They referred to the failure of the compound parallel arrangement, where there might be too little current, and, therefore, inefficiency on one side and too much or danger of breaking on the other. That was the real invention, namely, joining the middle of a compound parallel system to a split dynamo, or the middle of two dynamos in series. Why should not one set of two lamps be an instance of it? Because the essence of the invention was the joining of the middle points of two bridges. They could not have a single parallel line. In the Inchicore arrangement the additional lamps were to be put in series, and not in parallel. There was nothing there to suggest it to workmen. At the Alexandra Palace additional lamps might have been put on in many ways. If the Alexandra Palace case did not suggest to those who set it up, the plaintiff's invention, how could it inform the public? The only lamp, then, which would work in parallel was the Gülcher. Crompton's would not so work, and hence would draw him off the track of invention. Sir Horace Davey's argument about the rights of the public to substitute parallel for a single arc lamp was pure nonsense. Of course the public had the right to do what the plaintiff did, namely, invent this system; but no one did it. It was not fair in questions of subject matter to take an almost successful attempt instead of the standard public knowledge at the time. If one could, then Dolland could not have patented the achromatic glasses, because Newton had very nearly hit on it and had left a written record of his experiments. Prof. Thompson, in his lectures at the Crystal Palace, never thought of or suggested the three-wire system. The nearest approach to the invention was the compound-parallel arrangement. Dr. Hopkinson made the real invention. He knew of no case in which the alleged anticipations omitted an essential feature of an invention, and the inventor solved the problem, where it was held there was no subject matter. The Andrews arrangement was only the known compound parallel.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 11, 1892.

Electric Traction.—At the American Institute of Electrical Engineers last week three electric railway Papers, read at the Chicago meeting last summer, were discussed by railway engineers. Among those who took part in the discussion were Messrs. Sprague, Hutchinson, Emery, Leonard, and others. The general result of the discussion was that the series system of electric traction, very beautiful in theory though it might be, was not practicable, and could not in any way compete with the multiple system. Much severe criticism was made on Mr. Leonard's electric traction system, but he maintained his own part in the argument in good shape, and it was unanimously conceded that it would be time enough to decide on the merits of his system when the installation, which is now being made, had been given a practical test in actual service. Dr. Hutchinson resurrected some very uncomplimentary remarks made by Prof. Short about five years ago regarding the multiple series system of electric traction, and used them in a decidedly commercial way for maintaining his point, that the series system was not practicable.

The Niagara Falls Scheme.—It is announced that the Cataract Construction Company, which controls the water-power privileges at Niagara Falls, has settled upon the rates per horse-power to be charged to companies or individuals using power furnished for manufacturing purposes. The Niagara Falls Paper Company, using 3,000 H.P., is charged $8 per year per horse-power, and power may be used 24 hours in the day. The ordinary rates for power are $10 per horse-power for 5,000 or over, $11 for 4,000 H.P., and so on, down to $21 for 300 H.P. A 500ft. extension of the big tunnel has been determined upon, and is to be completed by February 1st.

NEW YORK, *November* 18, 1892.

The Meeting of the American Institute of Electrical Engineers.—The seventy-first meeting of the Institute was held on Tuesday, November 15th, and the Paper read by Dr. J. B. Williams at Chicago last June upon "Oil *versus* Air as an Insulating Medium," was brought up for discussion. A quadrant electrometer and other apparatus necessary for careful insulation tests had been set up, and the members were enabled to see various insulating substances subjected to practical tests. A number of oils were tested with layers of various thicknesses, and it was shown that paraffin oil was a very much better insulator than cotton seed oil, while rosin oil was far superior to either. The various manufacturers of insulated wire had sent in samples, and some of these were tested. On account of the lack of time and proper facilities it was impossible to make accurate comparisons between the various forms of insulation, and Dr. Williams offered to test all the samples in his own laboratory in the presence of such members of the Institute as cared to witness the tests, and report the results at some later date to the Institute. This offer was accepted.

Rapid Transit in New York.—It would appear that rapid transit in New York City is progressing slowly. The Rapid Transit Commission has issued the specifications and terms of sale of the franchise for the proposed underground road, the plans for which were published nearly a year ago. The franchise is to be sold to the highest bidder at the City Hall on December 29 next. The terms of sale, as announced by the commission, make it evident that they have taken special precaution that no stock-jobbing concern shall control the rapid transit facilities of the city. The terms of sale require 10 per cent. of the amount paid for the franchise to be paid in cash, and the remainder within 30 days. The successful bidder must deposit with the City Comptroller $1,000,000 in cash, and file a two-million dollar bond with the Mayor as security for the faithful peformance of this important work. The successful bidders may form a company to build and operate the road, the capital stock of which shall be $50,000,000, and it may issue bonds to an equal amount if found necessary. No one dares predict at the present time whether this franchise will find a purchaser or not, as many think that capitalists will

Hosted by Google

not care to invest such an enormous amount of money in a system for rapid transit which will parallel so many existing lines fully equipped for the carrying of passengers, although, to be sure, at a much lower rate of speed. The specifications call for the operation of the road by some means which will not require combustion in the tunnel; and as the trains must run at a speed of 40 miles per hour this, of course, means that the motive power will be electricity, Here is a problem for American electrical engineers, the solution of which will require their best abilities, and for which the extensive experience in street railroading has given electrical engineers an excellent preparation.

Gilbert's "De Magnete."—While the Gilbert Club in England has been spending several years in the translation of "De Magnete," and have carefully stored away the guineas which English-speaking people in all parts of the world subscribed for the promised copies of an English edition of this famous work, an American author and publisher have got out an edition of the book, which is about to be placed on sale. The work is a translation of the 1600 edition made by Mr. P. F. Mottelay, and will be issued from the press of John Wiley and Sons at an early date. It may be of interest in this connection to note that copies of the original edition of Gilbert's work are now selling in this country for $65 and $70, a copy at the former figure being sold last week. The rarer edition of 1628 does not often turn up, but a copy was, we understand, offered a few days ago at slightly less than $100.

The Chicago Exhibition.—The American electrical public has been somewhat excited over the prospect of the closing of the World's Fair gates at seven o'clock in the evening. It is doubtful, however, if it was ever the intention of the authorities to make a cast-iron rule of this kind, but reports a week ago were abroad to that effect. It is highly probably that evening exhibits will be permitted, although many departments of the Fair will have to shut down at seven o'clock. Very little news is available at present regarding the exhibits to be made by American electrical firms, but it is evident that the General Electric Company will make a display commensurate with the business it carries on in this country. The temporary office has been opened by this Company in the Horticultural Building on the Fair Grounds, and Lieut. Spencer is in charge of the preparation and arrangement of the exhibits. Herr Carl Haller, the engineer of the Imperial German Commission for the World's Fair, has arrived in Chicago, and has taken up the work of looking after the engineering features of the exhibit made by the German Government.

CORRESPONDENCE.

EARTHING THE MIDDLE WIRE.

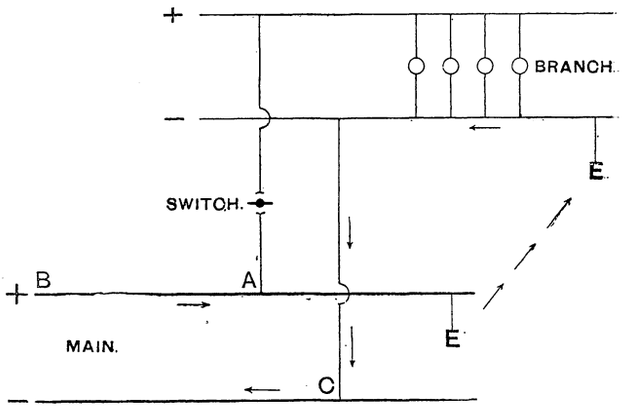
TO THE EDITOR OF THE ELECTRICIAN.

SIR: I read with great pleasure Mr. Human's letter in your last issue. Many of us who, as electrical engineers, have to deal with these questions have long since come to the same conclusion, but up to the present it has seemed almost useless to mention the question of earthing one of the conductors in any system. Now, however, that a fire-office inspector himself broaches the question and is actually convinced that it is the right thing to do, I venture to trouble you with a few remarks, hoping that I may be of some small assistance to him in meeting the objections of his colleagues.

The real question of the day is of course that of earthing the middle wire in three-wire systems supplied from central stations. It is obvious that, with the middle wire put to earth, it is a matter of impossibility for any part of the circuit to be raised more than 100 or 110 volts (as the case may be) above the potential of the earth. With all wires insulated, however, it is possible through an accidental earth on one lead to raise the middle wire 100 or 110 volts above the earth, and the other wire 200 or 220 volts. It is a fact well known to those who have tried it, that the shock to be obtained under these circumstances is not pleasant, whereas with 100 or 110 volts it is scarcely perceptible. Again, it is obvious that a difference of potential of 200 to 220 volts is far more likely to find out weak places in insulation than 100 to 110 volts.

In a properly-arranged system with the middle wire to earth, any accidental earth contact, or partial earth contact, on either of the insulated mains would cause the local cut-out to fuse, immediately extinguishing the lights and localising the fault within fairly narrow limits. It would be a matter of impossibility to light these lamps again until the fault had been removed. Another point of very considerable importance is that half of the fuses at present *supposed* to be in use would be no longer necessary.

It is clear from Mr. Human's letter that fuses were not fitted in each lead or, at any rate, not on each pole at the root of the branch in question, otherwise the fire could not have been caused as he supposes. The usual rule that every branch must be protected by a fuse on each pole which will act before the smallest wire within its district of protection can have enough current passed through it to cause heating was not observed. Mr. Human omits all mention of fuses and, taking his letter literally, one might infer that he was content to put up with the danger which he points out whilst the switch was on and the lamps lighted so long as it ceased when the switch was off. Of course he does not mean this. Things must be made just as safe when the lights are on as when they are off.



Reproducing Mr. Human's diagram, if there were any fuse at all in the branch it must have been in the switch wire, probably at A. Assuming now that all the negative wires were already purposely earthed, the damage at E on the branch, whatever it might have been, would make no difference in any way. The earth at E on the main would, however, immediately blow out the main fuse at B and the lamps could not be again lighted until the fault had been rectified. This would appear to give about as great security from fire risk as anyone can wish to get.

Assuming on the other hand that neither of the wires were earthed and that the proper system of double pole fuses was in use, there would naturally be a fuse at C. Either E on the main or E on the branch might exist alone for any length of time without anything happening, but the moment the other appeared, the fuse at C would blow out; *not that at B.* An ordinary wireman, if sent to put things right, would naturally examine the fuses at the root of the branch in question before doing anything else; and finding C blown out, would test and discover the earth at E on the branch. Having set this right, he would replace the fuse at C, switch on the switch, see that the lamps lighted up and go away quite happy. The earth, E, on the main would thus be left to assist in many a similar accident.

The advantages in using concentric cables and fittings must be so obvious when once the principle is granted that I need not mention them here, but Mr. Human speaks of difficulties in using concentric systems in connection with existing installations on other systems. I presume the difficulties he refers to would arise in the existing installations and not in the newly-fitted concentric ones. The only difficulty, however, appears to me to be in regard to the fuses and possibly, also, to the switches. It certainly would be necessary that every house wired on the present system should be carefully examined

Hosted by Google

throughout and all the switches and fuses arranged upon the insulated side. Doubtless this would be a somewhat troublesome business, but surely it is not insurmountable.

In conclusion, I wish to point out that the same complete system of fuses which is so obviously necessary in houses, would be a very great advantage if applied to all street mains. Every section of network between the feeding points should be protected at each end by fuses, and every branch street main proceeding from any section of network should again be similarly protected. An earth on any section or sub-section would then be automatically detected no matter where it occurred, and it would have to be set right before the supply through that section could again be started. The question of putting fuses in street mains would be of no interest to the fire offices, but would only be one of convenience to the supply companies. I believe, however, that some central station engineers have strong views against using them.—Yours, &c.,

Harlesden, N.W., Nov. 29, 1892. W. A. CHAMEN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have had the opportunity, through the kindness of Mr. Sheppard, of the North British Insurance Company, of inspecting the result of the fire in Regent-street, which has called forth the very able letter of Mr. Human. The woodwork of the columns to which the lights were fixed had been removed, and I found the leading wires entered the window at the roof within an inch of the top of the iron column, and proceeded toward the centre of the window, in casing, to a ceiling rose. From this rose flexible leads, I am told, were taken back to the lights on the columns. Everything being charred and destroyed, there is no direct evidence as to the origin of the fire, and there being current on only one wire at the time I could deduce no other cause for it than that given by Mr. Human. The installation, so far as I examined it, is carried out according to best modern practice, with wood casing, and, I am told, was examined and passed by Mr. Heaphy.

This is now the second important fire which has been laid to the charge of electric light in London, the other being Scott's restaurant, insured in the Phœnix Fire Office; and as both of these installations have doubtless been carried out in the best manner, so far as it is possible with wood casing, it must be obvious that the fault is radical to the system.

Mr. Human pays a tribute to the system I have nursed which, if it could but be universally introduced, would entirely overcome the risk. The suggestion to earth one of the mains is an unquestionable step in advance, and would at once open the field for introducing concentric wiring, and be a safeguard to existing installations. The first step must be taken by the supply companies efficiently earthing one of the mains and turning over the defective sides of house installations to the earthed main, and cutting off those with both sides defective. Earthing one of the mains even without changing over defective installations would not increase the danger of fire materially if at all beyond what it now is, because, as a matter of fact, both mains are now well earthed so that the change could with ease be spread over several days. The cost of the change would, I feel satisfied, be entirely outweighed by the saving of leakage and damages now taking place.

The next point is whether the existing degree of insulation provided on one wire is sufficient. Upon what basis are we to make our estimates, should it be the commercial value of the leakage or the ideal degree of perfection? It is well known that the majority of defects take place in the mechanical contrivances and joints, and but seldom in the wires, and also that mechanically rotten arrangements test electrically good at times, especially at first. If the mechanical details are good, a high degree of insulation will not improve the safety; we may therefore take it that the commercial value of the leakage should be the basis. I am told that with gas 5 per cent. leakage is not considered excessive. I do not, however, advocate this degree with electric lighting, but I can see no reason to suppose that because one side is earthed any increase of insulation is necessary on the non-earthed side. At the same time it is equally important that the earthed wire should remain substantially covered with insulation, unless it is made of large dimensions. I speak on this point from long experience of earthed land installations, both with double and concentric wiring. The installations, therefore, would be carried out according to present practice, with the exception that all switches and fuses must be inserted in the non-earthed wire. A double-pole switch should still be required for the purpose of testing.

I cannot close this letter without remarking on the able and lucid manner in which Mr. Human has opened this subject.—Yours, &c., J. D. F. ANDREWS.

London, November 28, 1892.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Allow me to point out that Mr. Human, in his letter on the above affair, is advocating the adoption of a remedy likely to prove worse than the disease. In a three-wire system it is doubtless a debateable point whether the middle wire should be earthed or not; because by so doing the maximum strain on the insulation of either of the mains is reduced one-half. But there is no such reason in a two-wire system.

The adoption of this plan would simply introduce the objectionable features of third-wire earthing, as for instance, that one fault on the unearthed wire starts a leakage current at once. Supposing the switches were rigidly placed on the unearthed wire (as they should be), then the plan simply stops leakage currents in houses when the lamps are switched off at the meter, and this is surely not sufficient compensation for the loss of one-half of the effective safeguard from leakage at all. If a voltmeter alternately earthed from each main is kept in circuit at the station, and a minimum deflection fixed, after which any increased leakage must be looked for, the best has been done in the matter of safety in my opinion.

Special low resistance voltmeters would be required if the minimum insulation resistance of any system was found to be anywhere much below a thousand ohms.

With a three-wire system unearthed and the insulation perfect, the voltage to earth is one-half the maximum across the outside wires, say (200/2) volts—with the insulation of one side very defective it is, of course, 200 volts—and the question is whether (granting a failing insulation somewhere) it is better to have 200 volts against sound cable, or 100 volts against failing cable.

If both sides are failing, the question is one of a pressure of 100 volts through the resistance of each fault (when the middle wire is earthed), or of 200 volts against the added resistances of both faults, and the one is as likely to break down as the other. If the faults are dead earths, the station should discover this and trace them.—Yours, &c.,

J. SAYERS.

Electrical Dept., Midland Railway, Derby,

THE HOPKINSON METHOD OF CHARGING FOR CURRENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In common, I am sure, with all your readers I have been very much interested in Dr. Hopkinson's proposed alternative system of charging for current. I have not yet been able to work it out sufficiently in detail to see how it would affect the circuits in which I am most interested. But it occurs to me that it may be worth while pointing out that if such a system of charging for electrical energy should come into use, a necessary adjunct of the ordinary meter would be some form of maximum recording ampere meter.

It would obviously be impossible to take as a maximum the particular number of lamps or points of connection applied for by a would-be consumer. The mere fact that he could use 8 and 16-c.p. lamps entirely at will makes this impracticable. The notion of using the main fuse as a measure of maximum current is also obviously out of the question. But there would be no difficulty in requiring each customer to state (no doubt, usually with the aid of his wiring contractor) the maximum current which he intends to consume, and I cannot suppose that the many engineers who are at work on the design of elec-

Hosted by Google

trical instruments would have any trouble in scheming a simple form of current indicator with a non return pointer which would be accurate within 2 or 3 per cent., as nearly as is necessary. —Yours, &c., ALEX. B. W. KENNEDY.

19, Little Queen-street, Westminster, S.W.,
November 25, 1892.

"EFFECTIVE" VOLTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Is it not high time that some definite agreement is arrived at respecting that unhappy word "effective" as applied to alternating E.M.F.? Dr. Fleming, in his Paper at present before the Institution, uses the term effective in exactly the same sense as Dr. S. P. Thompson applies to the term virtual. Dr. Thompson's definition of virtual being the square root of the mean square of either the maximum impressed volts or the maximum effective volts, according as impressed virtual or effective virtual is meant; Dr. Thompson meaning by effective the impressed volts, less the E.M.F. of self-induction.

But Dr. Fleming is not entirely consistent, for on p. 111, par. 13 of "Alternate Current Transformers," Vol. I., we are told that the effective E.M.F. driving the current is equal to the product of the ohmic resistance of the circuit and the cur rent at that instant in it—a definition precisely equivalent to Dr. Thompson's, as given above.

What must be the state of mind of the poor student between such conflicting statements can be better imagined than described.—Yours, &c., ROLAND S. PORTHEIM.

12, Station-terrace, Church-lane, Woolwich.
November 29, 1892.

[The words "virtual" and "effective" are both unsatisfactory; but the former is used to denote the value of the quantity (amperes or volts) as read by alternate current instruments. Our correspondent quotes a definition of the word virtual, which is not "precisely equivalent" to Dr. Fleming's, and we much doubt whether Dr. Thompson ever defined "virtual" as the square root of the mean square of a *maximum*.—Ed. *E.*]

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Some time ago an agitation was started and carried to a successful issue through the medium of your columns against the neglect of submarine cable and telephone interests in the Council of the Institution of Electrical Engineers. In consequence of that agitation the Council amended its ways, and recommended Sir James Anderson, Sir Henry Mance, Sir Albert Cappel, and Colonel Jackson, to fill the vacancies at the then pending election.

Since then two of these gentlemen have dropped out whether by their own desire, or by the working of the Society's rules, I am unable to say. But the point to note is that, instead of electing other gentlemen from the same professions to fill the places of Sir James Anderson and Sir Albert Cappel, the Council have reverted to their old loves, and have recommended still more electric light representatives. The good effected a few years ago is thus gradually being destroyed, and the Council is becoming what it was before, a close corporation of professors and electric light men, with a sprinkling of Government officials from the Post Office.

Your columns have recently echoed with the complaints of gentlemen who are dissatisfied with the composition of the Council and the neglect of their particular interests, and I am afraid that Prof. Silvanus Thompson's good-humoured fun, which he pokes at them, will be unable to get over the obvious facts or allay the discontent which has, with persistent obstinacy, "dogged the footsteps" of the Council for the last seven or eight years. They appear to have forgotten the lesson of the last agitation, and to have learned nothing in the interval. Is it too late to prevent the threatened extinction of the advantage we gained such a short time ago?—Yours, &c., C.

December 1, 1892

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The Belfast Harbour Commissioners invite tenders for the lighting of Queen's Quay, Abercorn Basin, and the Hamilton Graving Dock by electricity. Mr. George Combe, electrical engineer, of High-street, Belfast, will supply all information, and tenders must be sent in to Mr. W. A. Currie, secretary, on or before December 12th. Further particulars will be found in our advertisement columns.

——— The Directors of the North-Eastern Railway Company invite tenders for telegraph stores, including apparatus, wire, and line stores. Particulars can be obtained on application to Mr. Graves, Telegraph Department, York, and tenders must be in by noon on Tuesday next, the 6th inst.

——— Tenders are invited for the erection of an electric lighting plant at Villena, province of Alicante, Spain, and the lighting of the town for 50 years. Tenders to the Ministry of the Interior, Madrid, by the 15th inst.

——— In reference to the Note in our last issue relative to the proposed lighting of Santiago, Chili, by electricity, we may add that a specification and a plan of Santiago can be inspected on personal application at the Commercial Department of the Foreign Office, on any week-day between 11 and 6.

TENDER ACCEPTED.—The Staffordshire County Council have given the contract for the electric lighting of the Werrington Industrial School to the Electric Construction Corporation of Wolverhampton.

DISSOLUTION OF PARTNERSHIP.—Joseph Thorngate Woodham, Walter Smith, and Charles Henry Fuessli, carrying on business as electrical engineers and contractors, at Ducie-chambers, 57, Market-street, Manchester, as Woodham, Smith, and Co., have dissolved partnership so far as regards Charles Henry Fuessli.

BUSINESS CHANGES.—Arrangements have been completed for the transfer of the works at Swansea for copper smelting and rolling, yellow metal rolling and spelter making, and the goodwill of the business of Messrs. Pascoe, Grenfell and Sons (Limited), to the firm of Messrs. Williams, Foster and Co. (Limited), of Swansea and London, who will now carry on these works in addition to, and in conjunction with, their own Morfa Copper Works. The combined works of the Company will now form the largest establishment in the kingdom for rolling copper and yellow metal.

BELL'S ASBESTOS COMPANY (LIMITED).—The new premises of this Company are to be known as 59½, Southwark-street, instead of Southwark Bridge House, as formerly notified.

MESSRS. H. C. PARKS AND CO.—This firm send us their latest price lists of "Buffalo" Driving Belts, &c., for which they are agents in this country.

MR. F. M. NEWTON.—From the Newton Electrical Engineering Works we have received an illustrated price list and catalogue of the Taunton dynamos, Newton-Hawkins patent brush-holders, switches and switchboards, and the Newton arc lamp and transformer. This is another price list which shows great care in preparation, and the illustrations, printing, and binding are all that can be desired.

MESSRS. BARCLAY AND SON.—This firm have just completed an installation of the electric light at the large offices of the Bovril Company, in Farringdon-street, E.C.

E.P.S. STORAGE BATTERIES.—The Electrical Power Storage Company announce that during the past ten years no less than 10,000 tons of E.P.S. Storage Batteries have been manufactured.

RESIGNATIONS.—We are asked to state that Mr. E. J. Tumber has resigned the position of general manager to the Electric Stores (Limited).

——— Mr. A. Slatter asks us to state that he has retired from the Planet Electrical Engineering Company (Limited), and has joined Messrs. Julius Sax and Co. as their manager.

——— Mr. F. Dagger has resigned his position as Superintendent of the Plymouth District of the National Telephone Company, and his connection with the Company will cease on the 28th instant. Mr. Dagger has been 11 years in the telephone service, having served with the Lancashire and Cheshire Company and the Western Counties and South Wales Telephone Company, and finally with the National Company.

SMOKING CONCERT.—Messrs. Drake and Gorham's *employés* held their first smoking concert for the season on Wednesday last, at which more than one hundred of the staff were present.

Hosted by Google

ARDROSSAN.—The electric light which has recently been utilised for harbour illumination at Ardrossan, in the West of Scotland, has proved a complete success. The loading and clearing of vessels at night is much facilitated, and the saving in time is considerable. Seventeen arc lamps are at present used in the installation, and reserve dynamo power will allow of three further lamps being installed when necessary.

HOTEL LIGHTING.—The installation at the Great Northern Victoria Hotel, Bradford, is now complete, and consists of about 600 lights. Wiring is carried out on the sub-circuit distribution plan. Two pairs of heavy main cables are carried up the side of the lift, from which two branch cables are run to the distributing boards on each floor. The wire casings are neatly run on the corridor walls under the mouldings, where they are hardly noticeable, and in the bedrooms the casings have attached to them an ornamental picture mould 18in. from the ceiling, upon which a small bent bracket with 18in. projection is fixed from a suspension fitting with lamp and shade drops. The hotel is also connected throughout with electric bells, with a new design of semaphore fixed outside each door. When the button in the room is pressed, a real flag drops out of a slot in a semaphore box, and indicates to the servant the source of the call without the necessity of referring to the indicator. This flag is replaced by hand. Telephones connect all the managerial departments. The installation throughout is complete, and has been carried out by the Woodhouse and Rawson branch establishment at Piccadilly, Bradford.

BARNARD CASTLE.—At the last meeting of the Local Board the Lighting Committee notified that their report respecting the installation of the electric light was in preparation. It was proposed that the committee continue their investigation with regard to the lighting of the town with electricity and the cost.

MILL LIGHTING, &c.—The Electrical Engineering Company of Ireland have recently installed the electric light at the York-street Flax Spinning Company's Mill in Belfast. This is the first trial in these mills of using the electric light over the looms, and it has given so much satisfaction that a considerable extension of the plant is contemplated. A Crompton dynamo is used.——The same Company have also just completed a large contract for Messrs. Clery and Co., in Sackville-street, consisting of 18 Brockie-Pell arcs and 50 incandescents, the current being taken from the Corporation's mains. Other large installations are in hand, and the Company report a satisfactory increase in electric lighting orders, several theatres, hotels, clubs, and assurance companies' offices being included in the work in hand. They have recently built for Messrs. Lafayette and Co. a photographic arc lamp giving an illumination of about 15,000 c.p. This is placed in a parabolic reflector, is also automatic in action, and has hydraulic raising and lowering gear. This arc lamp, we are informed, has proved a great success.

BOLTON.—The Electric Lighting Sub-Committee of the Gas and Lighting Department of the Bolton Corporation held a meeting last week, at which it was announced that the members had had an interview with certain manufacturers of electric lighting plant, though nothing definite was decided at the meeting. Some important lighting developments are likely to result.

BRISTOL.—The members of the University College Engineering Society were last week invited to Gloucester to visit the works of Messrs. Fielding and Platt, and amongst the many features of interest described by Mr. Platt, jun., were the Company's electric welding plant. The current is supplied by a Crompton dynamo driven by a 50-H.P. Fielding and Platt gas engine, and Thomson-Houston welding machines are employed. The electric light is used over a considerable portion of these large works, and also in many of the adjoining engineering yards, including those of the Bristol Wagon Company, over which the party were also shown.

BROMLEY (KENT).—The Local Board are asking those willing to take up the electric light to fill up forms intimating the extent of their requirements.

CHATHAM.—The Board of Trade have notified the Chatham Town Council that they are satisfied that the Chatham and District Electric Lighting Company are in a position to carry out their electric lighting undertaking.

TRAIN LIGHTING.—As notified in our issue of the 18th ult., the London, Brighton, and South Coast Railway Company have decided to augment the number of trains electrically lighted running over their system. We understand that the electric light has proved a great success, and has given the Directors of the Company much satisfaction. The trains meet the requirements of railway working better than gas-lighted trains, inasmuch as they are ready at any time for whatever service they may be required, whilst it is necessary for the gas-lighted trains to be shunted to convenient places for charging. Considerable additional expense is entailed in this latter arrangement.

DUNDEE.—The Property Committee of the Dundee Town Council have arranged for an installation of the electric light throughout the Town House buildings. The city architect is to invite offers for supplying the necessary apparatus. It is intended that the handsome electroliers which at present adorn the Town Hall should be utilised in the electric lighting installation. ——On Monday the Works Committee of the Corporation ordered the purchase of an engine, dynamo, and lamps for the electric lighting station, and a lightning conductor for the chimney stalk.

EDINBURGH.—At a meeting of the Town Council, on Monday, the Lord Provost gave an explanation of their position with regard to the Electric Lighting Order. The Sub-Committee had had the matter in hand, but the Town Council had been otherwise extremely busy, and he was anxious they should not travel too fast, as experience was being gained by other corporations, from which they would benefit. He proposed they should enlarge the powers of the Lord Provost's Committee, who were dealing with the subject, as they would now have to take prompt action. They must consider the system to be employed, and whether the work should be done by the Council or be leased to a Company. It would be necessary to select an expert, and it would be advantageous for a number of the members of the Town Council to inspect some of the best systems and stations. These suggestions were supported by Bailie Dunlop, who said he had been lately in the North of England, and had got more information when in Bradford than he could obtain from a whole volume of reports. It was agreed to appoint the deputation at the next meeting of the Council, and that extended powers should be granted to the Lord Provost's Committee.

FREUCHIE.—Messrs. Lowdon Brothers, of Dundee, are lighting the Eden Valley Works, Freuchie, for Messrs. W. Lumsden and Son. The installation is to consist of 100 16 c.p. lamps, an Elwell-Parker dynamo being used.

HARWICH.—The Public Health Committee recommend the Town Council to dispose of their rights under the Harwich and Dovercourt Electric Lighting Provisional Order to a private firm.

HEREFORD.—This town has not hitherto shown much energy in the introduction of the electric light; but Mr. Hancocks, of Wide Marsh-street, has set his neighbours a good example by introducing the light into his residence.

ILFORD.—A deputation from the Ratepayers' Association of Ilford has waited upon the Local Board to urge upon them the necessity of introducing the electric light, and complained of the quality of the gas supplied and the charge made for it. The Chairman said the Board would consider the question. He had made every effort to get the price of gas reduced, but without success.

KIMBERLEY.—At a large dog show held at Kimberley recently, Messrs. John Davis and Sons, of All Saints' Works, Derby, provided a successful installation of the electric light, the plant consisting of a 100-H.P. dynamo driven by a 7-H.P. portable engine, the work being completed within seven hours.

KINGSTON.—At the last meeting of the Town Council the Mayor informed the members that, the Lighting Committee having asked Mr. W. H. Preece to undertake the duty of advising them in the matter of the electric lighting of the borough, that gentleman had written stating that he was unable to undertake the work, notwithstanding that as a resident in the neighbourhood he took a great interest in the scheme. Under those circumstances, it was proposed that the Council be authorised to obtain a report from an electrical engineer to be selected by the Committee. They had already had a report from Mr. Shoolbred, but were desirous of obtaining all further information possible, and did not mind some additional cost being incurred.

LECTURES.—Mr. H. Hall, after delivering a lecture at Johannesburg, on "Electric Light and Electric Energy," notified his intention of pushing forward the subject of the study of electricity in Johannesburg and announced that, with that object, he had decided to start a series of lectures and classes, to which those who were unable to pay for a course would, under certain conditions, be admitted free.

——— Mr. R. A. Lehfeldt delivered the third of a series of lectures on electricity at Firth College, Sheffield, on Saturday last, the subject being "Systems of Distribution." The lecture proved interesting to a large audience, and at its conclusion Mr. Lehfeldt received hearty applause.

——— Mr. A. Balance delivered a lecture last week on "Practical Electric Lighting" before the members of the Hull Scientific Club, Hull. A large number of members of the Club attended, and a hearty vote of thanks was accorded the lecturer at the close.

Hosted by Google

LECTURES.—Dr. Howard gave a lecture at the Picton Lecture Hall, Liverpool, on Tuesday last, entitled "The Distributon and Storage of Electricity."

——— Mr. H. L. Callendar, M.A., delivered a lecture at the Technical Schools, Plymouth, on Monday last, on "Dynamo Electric Generators," illustrated by lanterns, slides, and experiments.

LEDBURY.—Mr. J. C. Davies, of Fair Tree Farm, Ledbury, has installed the electric light at his brick works and residence, the necessary power being obtained from an engine used at the brick works.

LIVERPOOL —It has been decided to instal the electric light in the council chamber and ball room of the Town Hall, and the Corporation surveyor has received instructions to supervise the work. The estimated first cost is about £360. A cable is to be provided capable of being utilised should the Corporation decide to extend the installation. The Liverpool Electric Supply Company (Limited) have received the order for the work, for which, as far as possible, the gas fittings will be adapted.

LONDON COUNTY COUNCIL.—In connection with the decision of this Council to undertake their own contract work, it has been decided to appoint a chief of the new Works Department at a salary of £700 a year. The Council cannot be accused of erring on the side of liberality. As manufacturers of electric lighting plant, machinery, and apparatus are likely in the near future to have considerable business with the gentleman appointed to this onerous position, the trade should bring what influence it has to bear upon the selection of the right man.

MORPETH.—The introduction of the electric light to one of the large mills in Morpeth has given rise to a desire for a more considerable installation for general lighting. It is proposed by those who have the matter under consideration to utilise the motive power from the river, the plant for which could be erected at a comparatively small cost. The local press are taking the matter up, and it is probable that some steps will be taken shortly to advance the consideration of the subject by the proper authorities.

PRIVATE BILLS.—Only one application is down in the Private Bill List for the ensuing session of Parliament for a Provisional Order to supply electricity for public and private purposes in Scotland. This has been lodged by the Commissioners of Police of the Burgh of Partick, who ask for power under another Order to transfer their powers or liabilities to any other Local Authority, company, or person.

RAMSGATE.—The Corporation of Ramsgate have decided to oppose the bill of the Municipal Electric Lighting Company for a Provisional Order for lighting Ramsgate.

SELKIRK.—The extensive woollen factory of Messrs. G. Roberts and Co. has just been lighted by electricity, gas being entirely dispensed with; and the estate of Mr. S. Steel, at Philiphaugh, is also to have the electric light installed. There are 500 lights in the woollen factory installation, and these are giving entire satisfaction.

SWINDON.—At the last meeting of the Swindon Local Board it was decided to advertise for tenders for the laying of mains and services for lighting by electricity all streets in respect of which notices have been served, and that negotiations should be opened for the purchase of a site for an electric lighting station, and that tenders be invited for lighting by electricity Milton-road, Commercial-road, and Victoria-road, Swindon.

TEIGNMOUTH.—The Local Board have been requested to call a public meeting to discuss the question of lighting the town by electricity.

TELEPHONIC COMMUNICATION BETWEEN CASUAL WARDS.—The St. Marylebone Board of Guardians have again addressed a communication to the Local Government Board calling their attention to the desirability of placing the casual wards of the metropolis in telephonic communication; also suggesting that a conference should now be held of representatives from the several unions, and of the Board's inspectors, in order that an endeavour may be made to secure as far as practicable uniformity in the arrangement for the relief of casuals in London.

THETFORD.—At the meeting of the Thetford Board of Guardians last week it was decided to obtain estimates for both gas and electric lighting for the local workhouse. Reference was made to the recent calamity at the South Molton workhouse, and the desirability of selecting the safest possible illuminant.

WREXHAM.—At the meeting of the Wrexham Town Council on Tuesday it was resolved that negotiations should be re-opened with the Wrexham and District Electric Supply Company (Limited), with the object of the Council purchasing their undertaking.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

November 3, 1892.

19,821. SIEMENS BROS. AND CO., LIMITED. London. Improvements in alternating current transformers for variable loads. (Messrs. Siemens and Halske, Germany.)

19,834. A. R. BENNETT. London. Improvements in and relating to telephonic switching apparatus.

November 4, 1892.

19,874. E. P. DAVIS and A. C. COLLINS. London. Improvements in means or apparatus for regulating the supply of electrical energy to lamps and other apparatus.

19,880. T. PARKER and A. E. ROBINSON. London. The manufacture or production of an improved anode for use in electrolytical processes.

19,881. P. W. D'ALTON and J. A. FLEMING. London. Apparatus for controlling electric pressure in alternating current circuits.

19,886. W. FULLER. London. Improvements in making house connections with electric lighting mains.

19,889. A. E. VIDAL and G. HERVIEW. London. An improved electric clock.

November 5, 1892.

19,910. P. G. EBBOTT and J. B. VERITY. Birmingham. Improvements in reflectors for electric and other lamps and lights.

19,916. C. T. J. VAUTIN. London. Improvements in electrical conductors and in means of making connection therewith.

19,919. G. F. DE SOLOMÉ. London. Electric light conductors.

19,927. J. KÖRNER. Liverpool. Improved means for lighting railway cars by electricity.

19,953. J. C. RICHARDSON. London. Improvements relating to the construction of electrodes for electrolytic purposes.

19,959. E. H. P. HUMPHREYS and W. FRIESE-GREENE. London. Improvements in the means or apparatus for measuring electricity.

19,960. E. H. P. HUMPHREYS and W. FRIESE-GREENE. London. Improvements in ammeters and voltmeters.

November 7, 1892.

19,992. R. PIPPETTE. London. An electric energy meter.

20,009. F. SHAPLEY. Sidcup. A portable microphone for the improvement of hearing in deaf persons, and adapted both for individual and general conversation.

20,056. N. DURAND. London. Improved electrical appliance to be adapted to clocks for giving an alarm.

20,057. E. A. KUMBERG. London. Improvements in the construction of phonographs.

20,064. R. H. COURTENAY. London. An improved method of and means for generating currents of electricity for promoting the growth of vegetation.

20,065. R. H. COURTENAY. London. Improvements in the construction of horticultural buildings; also with apparatus and means for forcing the growth of vegetation by electricity.

November 9, 1892.

20,214. A. J. BOULT. London. Improvements in electrolytical apparatus. (O. Knöfler and Fr. Gebauer, Germany.)

November 10, 1892.

20,254. H. BOWN and W. HABGOOD. London. Improved arc lamp for photographic purposes.

20,316. H. CLEGG. West Norwood. Improvements in electric lighting.

20,333. C. E. L. BROWN. London. Improvements in apparatus for protecting transformers and other electrical apparatus from lightning and from electric currents of excessive strength.

20,348. R. J. BLACK. Manchester. Improved electric-battery cells.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

22,708. HELLESEN. Porous carbon for galvanic batteries.

1892.

37. WEBB. Electric tricycles.

14,886. WRIGHT. Electric switches.

15.059. GOVER. Electric incandescent lamps.

17,222. THOMPSON (Coffin). Electric metal working.

17,226. THOMPSON (Coffin). Welding metals electrically.

17,227. THOMPSON (Coffin). Welding metals electrically.

17,242. NEWTON (Carruthers). Electro-medical appliances.

17,304. AHEARN. Electric heaters.

17.321. AHEARN. Electric water heaters.

COMPANIES' MEETINGS & REPORTS.

National Electric Supply Company (Limited).

An ordinary general meeting of shareholders in this Company was held on Friday last at 119A, Fishergate, Preston. Mr. C. H. Cobbold, of Barnsley, presided. The CHAIRMAN moved the adoption of the report and statement of accounts as certified to Sept. 30th. The report gave an interesting *résumé* of the Company's operations in Preston. The machinery ordered, and in process of manufacture, will form a first instalment, with a capacity of 20,000 8-c.p. lights. It is estimated that, with the day and night service, the Company will be enabled to fix at least 35,000 8-c.p. lamps with this plant. Six miles of underground mains have been laid. A first-class central station in Bushell-street has been secured. It is to be thoroughly well equipped, and will be capable of supplying current to meet largely increased requirements at a small additional outlay. The expenditure on capital account amounts to £38,885, 8,045 ordinary shares have been subscribed for, and since the accounts were made up applications have been received for 2,380 additional shares. When these are fully paid, the share capital, including founders' shares, will be brought up to £52,625. As regards future prospects, the Directors consider they could not be more encouraging, there being an immediate prospect of remunerative business. The report of the manager and engineer, Mr. Bennett, went to show that, assuming the present rate of progress to continue, the result of the working for the three months ending December 31st will show a substantial profit.

The motion was seconded by Councillor MARGERISON, and unanimously adopted.

Mr. E. H. BOOTH moved, and Mr. HENRY CURWEN seconded, the re-election of Messrs. Titus Thorp and Ainsworth as auditors.

In accordance with a recommendation of the Board, Mr. John Booth, of Preston, was appointed a Director in place of Mr. Dan Rylands, who retired on account of his many engagements.

The CHAIRMAN, referring to the retirement of Mr. Rylands, said although that gentleman had a very heavy stake in the concern he had absolute confidence in the ability of the local men to manage the Company's affairs.

Mr. SEED (a shareholder) spoke in enthusiastic terms of the great success which had attended his application of electricity as a motive power in his own business.

Mr. F. F. BENNETT, the engineer, made a few remarks as to the prospects of the Company, and the meeting concluded with a cordial vote of thanks to the Chairman.

Swan United Electric Light Company (Limited).

The tenth ordinary general meeting of the shareholders was held at the Cannon-street Hotel, on Tuesday last, Mr. J. S. Forbes presiding.

The SECRETARY (Mr. H. Charles Gover) read the notice convening the meeting and the report of the Directors and accounts were taken as read.

The CHAIRMAN: Gentlemen—I think I will begin with the profit and loss account at once, because in explaining the items there I shall probably answer in anticipation some of the questions that might be put. First of all, let us take what we have sold. You will see that the sales, less commissions and allowances, amount to £9,498. 1s. 8d. I do not know if you have the same means as I have of getting at the facts, but if you refer to the accounts of last year you will find that the corresponding item at that time was £15,348. At the first blush, of course, it is rather a disturbing feature to find the sales in one year diminished from £15,348 to £9,498 in the following year. The figures look bad until they are explained. But the fact is that in 1891 we had quite a special sale of 100,000 lamps at a very fair price, and that came into the account of that year. Those lamps had been manufactured from time to time, and formed part of a large stock, and that favourable occasion offered itself to sell the block of 100,000, which we naturally did. If you take the realised price of those lamps you will see that the sales of lamps in connection with the local business, so to speak, of the Swan Company was about £5,348, and, therefore, bearing that in mind, the local or regular business has increased by about £4,000. Transfer fees and interest are slightly diminished, being £1,178, as against £1,290. From this it appears that people have not apparently been so anxious to transfer their interests in the Swan Company, and, as I dare say you are all aware, there is less money on interest account. This is a small item, but in this Company all small items have to be borne in mind. Dividend on shares in La Compagnie Générale des Lampes Incandescentes, less tax, amounts to £1,466, as against £1,168. This year that Company found itself enabled to pay 5 per cent. dividend, as against 4 per cent. in the previous twelve months. But I am enabled to say, incidentally, that, notwithstanding that the competition in France—I won't say has set in, because it has always existed—has set in with greater intensity, prices are coming down, and I think I may say that the current year shows that that Company will pay as good a dividend, and probably a larger one. That seems to be the opinion of our French colleagues. Dividends on shares in Edison and Swan United Electric Light Company (Limited) amount to £37,094, as against £34,799 in the corresponding period last year. That arose from the fact of the Edison and Swan, in a distribution, having been able to pay a larger dividend, and of course, as we have a very large share of our total capital invested in that Company, we participated in the improvement in its position. Now, stock is a matter of some moment, because upon the question of stock depends the final balance of the accounts, and I think when you understand it you will see the reason why we have paid, or rather propose with your permission to pay, 1 per cent. less than in the corresponding period last year. The stock brought forward was £18,449 in value, and this we have diminished to £14,654—that is a difference of about £3,800; so that if we had left the stock at its original figure we should have had this £3,800 to divide. But when I come to this question later I will tell you why we thought it right to reduce the value of the stock, and that question will naturally arise when we come to the opposite side of the accounts, namely, outlay. Purchases stand at £3,033; these mean the raw material in some cases, and in others manufactured material, but chiefly the former, which we work up into lamps at the factory. General charges include a variety of things—salaries, Directors' fees, rent, office expenses, income-tax, general and law charges—and amount to £3,6 .0. Wages and expenses at factory amount to £3,637, while sales ledger reserve is £300. The latter item we reserve to cover the risk of bad debts, because when the accounts are made up at the end of the year all our debts are not collected; but we find that a reserve of £300 leaves a fair margin to cover bad ones. The purchases include among other things the item of platinum. That is one of the elements, and that metal during the last two or three years has been a very errant quantity. Both the Edison and Swan and the Swan United were forewarned by competent judges that we should be wise to lay in a considerable stock of platinum, as the output of the metal, chiefly in Russia, was a very limited quantity and in the hands of a "ring," and, as its consumption, owing to the extension of the electric light, and, oddly enough, to the improvement of teeth on the part of American dentists, is enormously increasing. The course of trade is sometimes very singular, and many are the peculiarities that one finds out why this and that takes place in the market, and I must say I was surprised to find that the chief competitor with the electric lamp maker now is the American dentist. I can easily understand that in the particular article in which they deal—the continuity and preservation of teeth—it may be as valuable as it is in our lamps. However, we bought in advance upon the best advice we could get, and according to the best of our judgment a considerable quantity of platinum was bought. In the Edison and Swan Company we were fortunate enough to consume the greater part of it before a fall in the price of the metal had taken place. That, however, is not the case in the Swan United. We bought it at an average of about 60s., and we can now purchase it at 30s. In our short experience of ten years all sorts of fluctuations have taken place in the price; but, being face to face with the fact that our stock of platinum, from causes which I can only forecast—I cannot actually describe them—had fallen one-half, we thought it a prudent course to write it down by that amount in the balance-sheet. Very likely by this time next year we shall find that the price we have written down is less than the market value, in which case we may consider it desirable to write it up. Then again, we have, from the necessities of our business, a very large number of lamps in stock. Germany is a very big place, and we are obliged to keep lamps of a very great variety of types in stock. I have explained this many times before, but I must repeat it. In the different classes these amount to no great total, but when aggregated they reach a very large number, and you will readily see that this means a considerable amount of money locked up. We are face to face in Germany with severe competition—which I will tell you of presently—in this lamp business, as we are in France, and as, I suppose, we shall be in England sooner or later. We have written the lamp down from 9d. to 8d. Well, 1d. on 320,000 lamps is an appreciable sum, and those two items, together with some other matters of less moment, account for the slightly diminished dividend. Still we thought it more prudent to do that than to disburse 11 per cent., as we did last year. If we had been alive to the depreciation in the price of the lamp, or the price of the platinum, this time last year, we should have done then what we do now. What we have done is that we have put our balance-sheet on a sounder footing than before; we have brought it into line with the circumstances of the moment. Imagine what that means. In the production of a lamp, platinum at 60s. means 2½d., and at 30s. it means 1¼d., and when you are dealing, as we shall have to do, with hundreds of thousands of lamps that 1¼d. is a very material difference in the cost price of the article. We have established pretty well now that the greater the number of lamps we produce the less is the cost of production. In Germany what is going on at this moment is very German indeed. There are three companies who have resources enough, and knowledge enough, to carry on this lamp business. I suppose I am not treading on false ground when I say that, as far as we can ascertain, the universal opinion in Germany is that the Swan lamp—the one that we manufacture in Germany—is certainly as good and probably a better lamp than that of either of our competitors. We have to compete with Messrs. Siemens and Halske. Mr. Siemens' name we all know quite well in England in connection with electricity. His family are equally great in Germany. They are great manufacturers of dynamos, cables, &c., and are mixed up a great deal with the installation of the electric light, while amongst other things they make lamps, and they make these by some arrangement with the Edison Company and the Edison patents. Another great Company is the Allgemeine Elektricitäts Gesellschaft, who bought up Mr. Edison's patent for Germany, which we bought for Great Britain. As you know, the Swan Company bought Mr. Swan's British and Foreign patents, and the Edison Company, with whom we amalgamated, had only the British patents of Edison, and he sold his foreign patent to a combination. One meets with the lamps all over the Continent. The French have formed a Company of the Edison patent, and the German Edison Company are not only makers of lamps, but large installers of electrical stations. When Columbus made the egg stand on end on the table, a great many people, when they knew how, felt that they could do it too, so a great many people have learned "how," in these factories and emerge from them, get a little money together and start lamp making. The two companies that are our competitors have appreciated their position and have determined to kill all other little lamp makers. It is a horrible idea, unknown to us in England. What they call the survival of the fittest is going on in Germany, and my impression is that it will be a very efficacious process. When the fittest survive I suppose it is very

Hosted by Google

likely they may combine, and then the price of the lamp, which is now very low, may be so—what shall we call it?—regulated as to produce rather better results. That is our hope. That is what we have gone through this last year, and that is why our accounts and sales show a less favourable result than they might have done if the prices had been equal to the price of the previous year. Of course it will not do in this world to sit still and be put out of existence. We are now fighting the amiable game of trying to survive, and I think we shall succeed. Another feature—of course this is more or less problematical, but it seems possible—is that, with the depreciation in the price of the lamp, there is a possibility that the relative demand will grow. If you have to pay 2s. 6d. for a thing, you are likely to be a little more careful about the use of it than if you paid 1s. 3d. Well, now, to us it may be in the long run a matter of indifference whether we sell three lamps at 9d. or one lamp at 2s. 6d., because a very curious thing in connection with the business is that the profit is determined by the number of lamps you make. If we doubled the production of our present number we should probably produce a lamp at 2d. less than the present price. If we trebled it we might be able to reduce the cost still more. It all turns upon the number of lamps which are to be divided into fixed expenditure The market price is easily ascertainable. It is greatly influenced by the question of rent, by mechanics' wages, and all those charges which are high, relatively, to a small number, and low, relatively, to a large number. Therefore, from the view on this side of the table, although I find from some letters which we have received that some shareholders are a little disquieted about the reduction of dividend, what I should be prepared to state as a proposition, which is defensible by argument, is that, although we pay less dividend, our position is really sounder than it was this time last year. If you will again refer to profit and loss account, you will see that the balance carried forward is £34,840, against £39,000 in the corresponding half of last year, that is about £4,000 less, but then that balance represented stock in hand amounting to over £18,000, against the present balance of £14,654, which goes a long way to account for the difference in the figures. I shall be happy to answer any questions or give any further detailed information on the subject. Now, what are we to do with that £34,840? Well, we propose a course to distribute it after retaining a reasonable reserve. The balance from the previous account was £8,000 odd, and while on this subject I may just as well say that the reason why we carried forward so much as that was that we foresaw then that this question of price and the rectification of the balance-sheet was imminent, and we thought it prudent to bring over that considerable sum of money out of the earnings of the preceding year. We have already distributed in respect of the first half-year an interim dividend at the rate of 8 per cent. for the six months amounting to £14,558. We propose to distribute a further sum at the rate of 12 per cent. for the half-year, and, therefore, making, if you authorise that treatment of it, a dividend at the rate of 10 per cent. for the year. This will enable us to carry over about £6,000. I had better explain one of the items in the balance-sheet. The share capital stands at exactly what it was any time the last three or four years. There are 19 750 shares of £5 each, fully paid, or £98,750, and there are 78,949 shares of £5 each on which only £3. 10s. has been paid, making £276,321. That makes the capital of the concern £375,000 odd. There is an item in the balance-sheet which has disappeared—the item of forfeited shares, £3,500, which has been brought forward from time to time on one side of the account. It is of no good bringing it forward any longer. The shares have been forfeited. The money represented by the shares belongs to the Company. Instead of carrying forward an item which is calculated to mislead, we thought it better to knock it out of the account. If you carry your eye across the sheet you will see that the cost of Patent Rights, &c., represented by shares in Edison and Swan United Electric Light Company (Limited), with £208,478 paid; shares in La Compagnie Générale des Lampes Incandescentes, with £30,489. 8s. 3d. paid; patents held by the Company for Germany, &c., as per last balance-sheet, £332,449. 3s. 5d., less amounts received on account of forfeited shares and costs from the Allgemeine Elecktricitäts Gesellschaft £3,885. 11s. 1d., or £328,563. 12s. 4d. —that embraces the item of £3,500, the value of the forfeited shares, and some few hundred pounds which our friends in Germany had the pleasure of paying us, as the cost of the litigation referred to in the report. We have written that off the asset standing at £332,449, we have written it down to £328,563. Then we have got certain other items, outlay on factory, plant, &c., as per last account £1,570. There is an item which I might enlarge upon. We have got a factory in Germany, we hired a part of the large factory, being very suitable premises, with certain standing machinery, such as boilers and so forth, at a certain rental, and we go on paying the rent, but in order to make that factory efficient we had to spend £12,000 or £14,000, and as prudent people we thought we should begin early to write that down and we have done so. The stock in hand is £14,654, and is put in the balance-sheet as regards platinum at the current prices. There it is locked up just like so much gold in a bank safe. Investment in Prussian Consols cost £5,120; investment in new 2¾ per Cent. consolidated stock cost £29,004. 19s. 6d.; cash on deposit and in hand is £26,413. 5s. Now that is the whole story. I do not know that I need enlarge upon it, but having gone into such detail I may sum it all up. The first paragraph of the report contains all that I may say I have talked about. The profit and loss account for the year shows a credit balance of £34,840. 11s. 11d., which, together with £8,010. 3s. brought forward from the last account, makes disposable the sum of £42,850 15s. 9d. An interim dividend in respect to the first half of the year amounting to £14,558. 9s. 8d. has already been paid. The Board proposes that a further sum of £21,467 8s. 4d. be divided free of income-tax, and that £6,824. 17s. 9d. be carried forward. We have got rather a peculiar distribution. We have two classes of shareholders, fully-paid £5 and partly-paid £3. 10s. The fully-paid are entitled, up to 5 per cent., to rank on the money with the £3. 10s. Therefore they are entitled to the first dip into the bag to the extent of 5s. per fully-paid share, against 3s. 6d. per partially-paid share. But then at the next dip each shareholder takes half—that is per share and not per cent. Therefore, to get at the dividend we have to know how much per cent. it is. After that the division is on the principle of half and half, which caused a great deal of abstruse calculation. The distribution of this amount in accordance with Clause 77 of the Articles of Association will work out at at 4s. 2⅝d. per share on the 78,949 ordinary shares of the Company, £3. 10s. paid, and at 4s. 11⅛d. per share on the 19,750, £5 fully-paid, being equivalent to 10 per cent. per annum on the partly paid, and of slightly under that rate upon the fully-paid shares. Now comes a paragraph of some importance. As long as we were in litigation in Germany we suffered under the disadvantage of not knowing where we were. We could not push our trade because the German law is rather terrible on the subject of damages. The German law proceedings—are they as protracted as those in England? Well, pretty well, and probably a little more so, and until you get a decision of the Court you do not know where you are on two vital points—first of all as to the validity of the patents or otherwise; and secondly, as to the damages—that is to say, how much they will mulct you if you go on after an action is commenced selling something which may turn out to be an infringement. Well, as prudent men, knowing that there were doubts which had to be solved in connection with this action which had been running on for several years, we did not force our trade with any very great vigour. We took what came, and made the best of it. Well, it turned out that we were not infringers, and we incurred no damages, and were thus left to go on without the fear of damages, and to push our article without this shadow of apprehension hanging over us. We have sold most of the Swan business in the case of the English Company, in the sense of having amalgamated with the Edison patents to the extent of £208,500, in round numbers, of our capital. Well, then, we had a French complication, and we thought we had better cross there than fight. We made an Edison and Swan Company in Paris, and we have some £30,000 odd of our capital invested in that enterprise, which I told you last year paid 5 per cent., and shows a possibility of future value. Our partners there are very powerful people. They are not only manufacturers of lamps with us, but they are people who have got the installation of the electric light over large parts of Paris, and are in a large way of business in other ways; and they have the opportunity of forcing their lamps, and they are getting a very good average price. That agreement precludes the Edison-Swan Company from travelling on to the Continent at all, except in respect of Germany. In Germany we are free, and there we have got a manufactory. Here I wish to say that German thrift and German intelligence—and I must say, having seen a good deal of it myself in Germany, though I do not admire the principle of compulsory military service—German discipline amongst the workmen will be a great fact with us some day. The greater intelligence and better discipline ingrained in them by that service will enable you to deal with your workmen on much more reasonable terms than with workmen who have not had that compulsory training, so that given the number we shall be able to turn out lamps in Germany scientifically and mechanically as perfect, and at a less price, I fancy, than in either France or Great Britain. That is a very important lever for us. For some time we supplied our French friends with lamps made in London at a price less than they could produce the article at. We can now supply the lamps made in Germany at a great deal less than they can be produced for in Paris. But then comes the question, you cannot keep up a separate establishment to do a limited trade at an undue cost. Here we are allied companies. A large portion of our capital is invested in the Edison and Swan Company. We have made a portion of it safe in the French Company, and we have got the German residuum. What is that worth? If we can only ascertain what it is worth there is nothing easier than to put it in the pot with the Edison and Swan, and work as partners, not only in Great Britain but in Germany, and it might and probably will end in lamps being manufactured in Germany by German workmen, and for the benefit of the latter, instead of in London, where wages, &c., make it impossible to live at a profit. We think that the time has come when this residuum had better be brought in to the big company. We have got the largest share in the Edison and Swan Company. We believe that the latter will be greatly strengthened if they can absorb this German business with its advantages present and prospective. One advantage which would follow immediately would be a reduction in the cost of conducting the German business, because, with a separate Board of Directors and what they call location and separate administration, there is a certain waste. We say:—"The litigation on the German patents of the Company having happily terminated, and the bulk of the capital of the Company being now invested in the Edison and Swan Companies in Great Britain and France, the Board believe that the time has arrived when a fusion of the residuum of the foreign business of the Swan Company with the British Edison and Swan Company may be effected with advantage to both interests, and negotiations are pending with a view to effecting some arrangement in this direction." It will make both Companies richer and stronger. Mr. Quilter and Mr. Swan represent two very powerful elements on this Board, and Lord Lichfield represents a potent one in the Edison and Swan Company, and he thought, and I thought, that we had better resort to another gentleman who was a Director of that Company—Sir John Lubbock—whose position and ability make him specially valuable in a matter of this sort, and that all these gentlemen should think the matter out, and that they should come to some arrangement, to be submitted to the proprietors of both companies, under which the Swan Company should be merged into the Edison and Swan. I am not in a position to-day to say what point has been reached. The negotiations are pending. They have made a considerable advance. The parties appreciate the principle and they appreciate the advantages, but they are traders after all, and I do not know that they have arrived at the precise figure. The theory is that the Edison and Swan Company will purchase this residuum of the Swan Company for a commodity to be called Debenture Stock, bearing some reasonable rate of interest, but the parties are not agreed as to what this

Hosted by Google

interest should be. One party wants more than the other is inclined to give at present. I mention that in order that the proprietors may realise that there is something pending that will be greatly to the interest of the Company. Of course we shall have to call special meetings of both Companies before anything is done, and it will be for you to accept or reject the terms as you see fit. The next paragraph refers to the death of Mr. Leyland. Well, I will not enlarge on that. His death came on us so suddenly that it was almost tragic, and everybody connected with the lamp business and other businesses must have realised what a loss it would be to us. We felt it deeply, and in reference to the negotiations I have referred to I for one regret as far as I am concerned that we have not the support of that precise and clear intellect which was eclipsed in an instant. When he had gone we had to look round, and Major Flood Page, who had given us yeoman's service for a number of years, wished to be relieved of some of his more detailed labours, and we elected him to fill the vacant office in which he is now acting. Mr. Cuthbert Quilter was elected as Deputy-Chairman, who, of course, as everybody knows, is greatly responsible for the initiation of these companies, and whose valuable services I will not enlarge upon. Major Flood Page came on the Board in virtue of his knowledge. The Directors who retire by rotation are Mr. J. S. Forbes and Mr. W. E. Batt. Well, now, as I said, if you do not carry on this business as a separate business you will not want Mr. J. S. Forbes, Mr. W. E. Batt, Major Flood Page, and Mr. Quilter, and the machinery of administration and a separate office, so that there will be a sensible saving. I will not pledge myself to this, but I think that if the management of the Swan Company as it now stands, emerged from what makes a double Board of Directors essential, the expenses of administration would be reduced by £2,500 a year. That would make an important difference in the cost of the lamp. Further, I have told you the indirect benefits. Meanwhile the machinery must be carried on. I assume that if we do come to terms it will be on the theory of the Swan Company being fused into the Edison and Swan immediately, or as early as may be. A very convenient time would be, of course, on the issue of a balance-sheet for the complete year, and I fancy that it may turn out in this way. Meanwhile you must continue the machinery. I have made a rather long statement, but I trust not too long for the importance of the occasion, and having made it I shall be ready to answer any questions or give any further explanations that shareholders may desire. I now move

"That the report and accounts for the year ended September 30, 1891, be and the same are hereby received and adopted."

Mr. W. CUTHBERT QUILTER, M.P., seconded the motion.

The CHAIRMAN, in answer to Mr. Skipworth, said that in anticipation of any criticism he had told them that the expenses of the direction and the machinery were beyond all measure out of proportion to the work done. If the work of the Directors had been confined to the manufacture of lamps, the outlay certainly would be so; but up to almost recently their work had been to defend the legal position of the Company in a series of very difficult questions of law, and to save its capital. Take as an illustration—he agreed that the charge of £3,620 was a very large tax on so small a sale business as £9,498. Nobody could contest it; but then the attention of the Directors had not been confined to the manufacture of so many lamps. That was a very simple process. Their business had been to guide the policy of the Company and to prevent the property from being thrown away, which it would have been unless they had contested the actions in Germany. Now that was all over. The main *raison d'être* of their existence was at an end. Out of the £3,520 charged for salaries, Directors' fees, &c., the Directors got £1,500. They could, therefore, estimate whether that was a very extravagant reward to five gentlemen, individually or collectively, for a year's work of harassing litigation. He personally was the principal culprit, having received £500, but he was ready to forego it because he knew he was not now wanted, and his colleagues were in the same boat. The occasion was passed, and they wished the shareholders to have the benefit of every economy.

The motion was then carried *nem. con.*

The CHAIRMAN: I beg to move

"That in addition to the £14,558 9s. 8d. already distributed in respect of the six months ended 31st March, 1892, a further sum of £21,467 8s. 4d. be divided free of income-tax; to be distributed in accordance with the provisions of Clause 77 of the Articles of Association, making the total distribution for the year of £36,025 18s."

Mr. CUTHBERT QUILTER, M.P., seconded the motion, which was carried unanimously.

Mr. QUILTER then moved that Mr. J. S. Forbes be elected a Director of the Company, which was seconded by Major FLOOD PAGE, and carried unanimously.

Mr. FORBES having expressed his acknowledgment, moved that Mr. Edward William Batt be elected a Director of the Company, which Mr. CUTHBERT QUILTER, M.P., seconded, and it was carried *nem. con.*

Mr. DAVEY proposed, and Mr. BETTS seconded, the reappointment of the Auditors, Messrs. Welton, Jones and Co., and the motion was agreed to.

The CHAIRMAN said that he had received a letter from a stock and share broker, asking him to explain certain particulars in regard to the Company. The first point was "That lamps are now being manufactured under royalty and sold cheaper than the prices obtained by the Swan Company. Are they durable, and if such is the case, why are the lamps dearer, as I understand they are?" Now, as far as they knew, no lamps were being manufactured, certainly none under royalty. If there were any being manufactured they were infringements, and the Directors would prosecute the infringers. As to whether the lamps were durable or not he could not say, because he had not seen any, for no lamps were being sold under royalty. "If they are not durable can you account for the sale, as when the patent expires the other competitors will manufacture them to be sold even cheaper, as there will be no royalty?" That question was answered by the other, since the lamps were not manufactured. "Are the interests of the Directors still as large as before the depreciation set in, as from the transactions that have taken place recently it appears some heavy selling has been made?" The innocence of his mind was so great that he could not induct an insinuation from that. If he did it might be a little unkind. However, the holding of the Directors was the same. (Mr. Quilter: Rather larger). "Also when the royalties cease will the Swan Company not only feel this loss but also the keener competition, and to what extent are those royalties?" He did not know what that meant. Having the intention to force their wares they might feel the effect of competition, but he thought that they might look forward with hope and confidence to the future.

On the motion of Mr. WILSON a vote of thanks was accorded to the Chairman, who briefly returned thanks, and the proceedings terminated.

International Okonite Company (Limited).

The annual general meeting of this Company was held yesterday at the Cannon-street Hotel. Sir Alexander Armstrong, K.C.B., F.R.S., presided in the absence of Mr. S. Pope, Q.C.

A circular, which accompanied the notice calling the meeting, and which was signed by Mr. Samuel Pope, Q.C. (the Chairman of the Company), after stating that the report and accounts would be formally laid before the meeting, continued as follows:—"Since these accounts have been audited your Directors have been made aware of serious difficulties which have arisen in the administration of the Manchester factory, and which will necessitate their immediate and resolute interference. In addition to this, important engagements will prevent me from being able to be present at the meeting. It will therefore be proposed that the meeting formally held shall be at once adjourned until January 10, 1893. At that date it is hoped the whole of your Directors can be present to meet the shareholders, who will have had time to consider the accounts and report, and a complete reorganisation of the Manchester factory be accomplished and thoroughly explained to the shareholders."

Mr. JOHN C. WYLDE, the Secretary, read the notice calling the meeting, and the above circular.

The CHAIRMAN: Gentlemen—The letter of the Chairman will have prepared you for the motion which I am now about to make, viz.:

"That this meeting be adjourned until the 10th of January."

You will then have ample opportunity of fully considering the balance-sheet and of going into details, and the Chairman will then be in the position of affording you more information than I can do. I will therefore move that this meeting be now adjourned.

Mr. TOD seconded the motion.

Mr. JOHN KENYON (Manchester) wished to move an amendment that the business of the meeting be proceeded with.

Mr. GLADSTONE seconded the amendment.

Several shareholders desired to ask questions, but the Chairman said that he did not think it advisable at that meeting to go into details. The meeting had been called, in accordance with the requirements of the law, within 12 months of the last meeting, and it was now proposed that they should adjourn till January 10th, when full details would be given to the shareholders by the Chairman, Mr. Samuel Pope, Q.C.

Mr. MATHERS wanted to go into the figures of the accounts.

The CHAIRMAN declined to do so.

Several other gentlemen, including certain late servants of the Company, attempted to address the meeting, but

The CHAIRMAN ruled the remarks out of order, as being inimical to the interests of the Company.

A proposal to substitute some firm of auditors in Manchester in lieu of the Company's present auditors was ruled out of order by the CHAIRMAN, who declined to put it, on the ground that the re-election of auditors was not before that meeting, but would form part of the business for the meeting on January 10th. The Board had perfect confidence in their present auditors, Messrs. Price, Waterhouse, and Co.

Mr. GLADSTONE maintained that the business ought to be proceeded with at once (hear, hear, and no, no).

Mr. GRIFFITHS intimated his intention of taking action against the Company because the statements of the prospectus had not, he said, been borne out. He must not by his appearance at that meeting be taken as waiving his right to take action.

The CHAIRMAN said that there was no foundation in the statement that in the six weeks from now to January 10th the Company would go on making losses. He deprecated the action shareholders were taking. He promised to afford all information to the shareholders that could reasonably be given at the Company's offices.

After some personal discussion the amendment was put and declared lost by the Chairman.

The motion to adjourn until January 10th was then put and lost on a show of hands.

The CHAIRMAN then put in the proxies the Directors had received in favour of adjournment, and declared the resolution carried. He formally stated the meeting was adjourned until January 10th.

Mr. GLADSTONE challenged the proxies and their validity.

The Chairman allowed him to inspect them, and he found that they were quite legal.

The meeting then adjourned.

NEW COMPANIES, STATUTORY RETURNS, &c.

ARCAS PLATING COMPANY (LIMITED).—This Company was registered on November 21st, with a capital of £80,000 in £1 shares. The objects (amongst others) are to adopt and carry into effect an agreement, dated November 15, 1892, between the London Metallurgical Company (Limited) and Sherard O. C. Coles and Harold R. Braid on behalf of the Company, for the acquisition of certain patents and patent rights, particulars of which are not given ; to use, exercise, develop, grant licences in respect of, sell, or otherwise turn to account the said patents, and to carry on the business of plating in all or any of its branches, and any allied or kindred businesses.

AUTOMATIC ELECTRIC RAILWAY SIGNAL COMPANY (LIMITED).—This Company was registered on November 26th, with a capital of £10,000, in £1 shares. The objects are to acquire certain patents and apparatus for railway signalling, &c., and in particular to carry into effect an agreement dated November 25, 1892, between Reginald B. Annesley, George R. Leyland, Walter Emmott, and Robert W. Brown and Thomas Woodfine (on behalf of the Company), to establish and work automatic electric signals for railways and grant licences for that purpose, and generally to carry on the business of engineers, railway, tramway, and other signal manufacturers and dealers in railway, tramway, and other signalling apparatus, engines, and machinery. The first subscribers are : J. Bushby, Robert W. Brown, William H. Potter, Frederick T. Loftus, John Charnley, R. B. Annesley, and George R. Leyland, all of Liverpool.

ELECTRICAL AND GENERAL CONTRACT CORPORATION (LIMITED).—This Company was registered on November 25th, with a capital of £50,000, in £5 shares. The objects are to enter into or acquire by purchase or otherwise, and carry out contracts or concessions, or other grants in any part of the world, for making, purchasing, or working railways, tramways, telegraph and telephone lines, electric and other lighting, electric, hydraulic and other works, and for the equipment of such works with electric or other plant, stock or apparatus ; to carry on the business of contractors in any part of the world, and also the business of electrical and mechanical engineers, electricians, suppliers of electricity and electrical plant, and manufacturers of and dealers in electrical apparatus. The subscribers are:—

	Shares.
J. F. Mieville, 12, Angel-court, E.C.	1
W. S. Graff Baker, 35, Parliament-street, S.W.	1
Alfred de Turckheim. 35, Parliament-street, S.W.	1
H. Chester Masters, 1, Jeffrey-square, E.C.	1
Dillwyn Parrish, 2, Copthall-buildings, E.C.	1
George E. Church, Dashwood House, Old Broad-street, E.C.	1
Frederic Manuelle, 101, Leadenhall-street, E.C.	1

L. ALWYN (LIMITED).—This Company was registered on November 24th, with a capital of £2,000, in £1 shares. The objects are to establish and carry on the business of agent to the Brush Electrical Engineering Company (Limited), in the City of Bristol, and the neighbourhood thereof, and in such other cities and places as the Company shall deem expedient, such agency or agencies being for the wiring and fitting of premises and the erection and installation of machinery, and the sale of the same, incidental to electric lighting, as apart from all central station plant ; generally to manufacture or purchase, supply, sell and deal in all apparatus and things necessary for the electric lighting of shops, houses, and all other premises, apart from central station plant, and to carry on any other electrical engineering agency subject to the approval of the Brush Electrical Engineering Company (Limited).

R. C. CUTTING, DOUGLASS, AND COMPANY (LIMITED).—This Company was registered on November 22nd, with a capital of £12,000, in £5 shares. The objects are : To acquire the goodwill, plant, trade marks, and stock-in-trade, and take over as a going concern the business of electrical engineers and manufacturers of lightning conductors carried on by R. C. Cutting, Douglass, and Company (Limited), at Doctors'-commons, London, E.C., and to carry on the said and other businesses. The signatories (with one share each) are :—A. M'Keand, 11, Pancras-lane, London, E.C. ; G. W. Grosvenor, "Holywell," Lewin-road, Streatham, London, S.W. ; W. Bartholomew, Wardrobe-chambers, Queen Victoria-street, E.C. ; S. J. Skilton, Wardrobe-chambers, Queen Victoria-street, E.C. ; S. F. Alderson, 2, Nunhead-lane, S.E. ; J. Clark, 62, Finsbury-pavement, E.C. ; Stephen Graham, 1, Mary Villas, Hoe-street North, Walthamstow.

SIR JAMES FARMER AND SONS (LIMITED).—This Company was registered on November 23rd, with a capital of £50,000, in £10 shares, to carry on the business of machinists, mechanical and electrical engineers, machine and engineering tool makers, boiler makers, iron and brass founders, millwrights, metallurgists, and metal workers, carried on by the firm of Sir James Farmer and Sons at the Adelphi Ironworks, Salford, Manchester.

MONTE VIDEO TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to November 14th, has been filed. The Company was registered on July 31, 1888, with a capital of £180,000, divided into 24,000 preferred shares and 12,000 ordinary shares of £5 each. The capital of the Company was, in 1889, raised to £220,000 by the creation of 8,000 new shares of £5 each, of which new shares 5,000 were preference and 3,000 ordinary. 3,000 ordinary and 3,000 preference, considered as fully paid up, were allotted to the vendors in consideration for premises and property. At the time of making up, 28,000 preference and 15,000 ordinary shares had been taken up, and 3,000 of each class of shares issued as fully paid. Upon the remaining 25,000 preference and 12,000 ordinary shares the full amounts have been called, resulting in the payment of £185,000

PACIFIC AND EUROPEAN TELEGRAPH COMPANY (LIMITED).—The statutory return of this Company made up to November 2nd has been filed. All the shares in the capital of £100,000 in £10 shares have been taken up. £2 per share called, and all calls paid. At extraordinary general meetings of the members of this Company, held on October 19 and November 16, the following special resolution was duly passed and confirmed, viz. : "That the share qualification of a director, as provided by Article 59, shall not apply to Sir John Pender, G.C.M.G., M.P., who may at any time hold the office of and act as director without being the holder of any shares in the Company, and shall be eligible for election as a director, and may retain and exercise that office notwithstanding he may not be the holder of any such shares, and that the Articles of Association relating to the appointment and qualification of Directors be read and construed accordingly."

PETROLEUM ENGINE COMPANY (LIMITED).—The annual return of this Company made up to November 2nd has been filed. The Company was registered on March 26, 1888, with a capital of £100,000, in £5 shares. At the time of making up 18,261 shares were taken up, all of which had been issued as fully paid. Share warrants to the value of £485, comprising one share each, are outstanding.

RAILWAY ELECTRIC READING LAMP COMPANY (LIMITED).—The statutory return of this Company, made up to November 1, 1892, has been filed. Only seven shares of a capital of £100,000, divided into 16,000 ordinary and 4,000 deferred shares of £5 each have been taken up, the full amounts called and all calls paid (£35).

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—This Company have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income-tax, for the quarter ended September 30th last, payable on the 21st inst. The Company's transfer books will be closed from the 15th to the 20th inst. inclusive.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—Mr. J. B Braithwaite, jun., has been elected Chairman of this Company in succession to the late Duke of Marlborough, and has accepted the appointment for a period of one year.

CHILI TELEPHONE COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee for a quotation in the Official List of 4,000 additional shares, Nos. 40,001 to 44,000.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The Stock Exchange Committee appointed yesterday (Thursday) a special settling day in this Company's Six per Cent. Preference Shares, Nos. 1 to 20,000, and have ordered them to be quoted in the Official List.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended November 27th were £893, as against £806 for the corresponding period of last year, being an increase of £87. The total receipts for half-year amount to £17,900, against £16,173 in the corresponding period of 1891, being an increase of £1,727.

COMMERCIAL CABLE COMPANY.—This Company have opened a branch office in East India-avenue, Leadenhall-street, E.C., where messages are sent direct over the Company's system.

EDINBURGH ELECTRIC SUPPLY CORPORATION (LIMITED).—This Company are inviting applications for £80,000 in 16,000 shares of £5 each. The authorised capital is £100,000. The Company has an influential Board of Directors, and is established to supply electric light and power in Edinburgh, Leith, and elsewhere. The Directors calculate upon the probability of the Edinburgh Town Council asking for tenders for lighting Edinburgh, and desire that the Company shall then be in a position to tender. The amounts payable are as follows : – 5s. on allotment, and no further calls unless the Company proceeds to business, in which case, with two months' notice, calls are not to exceed £2 per share. If the Company does not proceed to business the allotment money will be returned in full, the Directors bearing the preliminary expenses. Issued with the prospectus is a lengthy list of persons who have offered to become shareholders in the Company.

EVERED AND CO. (LIMITED).—The Stock Exchange Committee have ordered the £10 paid shares, Nos. 1 to 6,744, and the £7 paid shares, Nos. L1 to L9,750, in this Company to be quoted in the Official List.

NATIONAL TELEPHONE COMPANY (LIMITED).—The Stock Exchange Committee have appointed to-day (Friday) a special settling day in this Company's Third Preference Shares, Nos. 1 to 90,950, and have ordered these shares and the additional Ordinary shares, Nos. 447,235 to 454,747, to be quoted in the Official List.

ONCKEN PATENT STAVELESS BARREL COMPANY (LIMITED).—At the statutory meeting of the shareholders of this Company, held on Wednesday, the Chairman (Mr. F. B. Maddison) announced that satisfactory progress was being made with the Company's business.

REUTER'S TELEGRAM COMPANY (LIMITED).—The Stock Exchange Committee have ordered 1,000 additional shares, Nos. 10,803 to 11,802, to be quoted in the Official List.

RIVER PLATE TELEGRAPH COMPANY (LIMITED).—The Second Division of the Scotch Court of Session, on Friday last, ordered intimation and advertisement of a petition by the River Plate Telegraph Company (Limited), of 188, St. Vincent-street Glasgow, for leave to alter the memorandum of association of the Company. The Company own a land

Hosted by Google

telegraph line from Buenos Ayres, in the Argentine Republic, to Monte Video, in Uruguay. They ask powers to let or hire out their property, or to amalgamate with other companies, the object of the alteration being to enable them to work in conjunction with the Brazilian Submarine Telegraph Company, whose line extends from Lisbon to Pernambuco, and with the Western and Brazilian Telegraph Company, whose line extends from Pernambuco southwards to Monte Video.

RICHARD HORNSBY AND SONS (LIMITED).—The balance-sheet of the Company at September 30th last shows a balance for the year of £19,234 10s. 7d., which, after paying interest on debentures and calls paid in advance, and dividend on preference stock, leaves the sum of £8,019 10s. 7d. available for dividend. Of this £3,750 was paid as interim dividend on June 15th. As already announced, the Directors propose the payment on December 15th next of a further dividend of 2s. 6d. per share, making, with the interim dividend, 5s. per share, carrying forward a balance of £519. 10s. 7d. to next account.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Nov. 25, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,079.

SALES BY AUCTION, &c.

Re A. B. Gill and Co.

SALE of ENGINEERING and ELECTRICAL FIXED and LOOSE PLANT, MACHINERY, DYNAMOS, MOTORS, ELECTRICAL FITTINGS, GAS ENGINES, PATTERNS, and other effects.

WHEATLEY KIRK, PRICE AND GOULTY are instructed by the Trustee, Arthur Clarke, Esq., TO SELL BY PUBLIC AUCTION, on TUESDAY, the 13th December, 1892, commencing at 10 for 11 o'Clock prompt, the ENTIRE CONTENTS of the EAST DOWN ELECTRICAL WORKS, Dermondy-road, East Down Park, Lewisham, S.E.

Comprising:—8-H.P. Vertical Engine and Boiler, by Davey Paxman and Co.; 6 and 14-H.P. Otto, 2-H.P. Stockport, and 2-H.P. Clark's Gas Engines; Six ¾-H.P. Electrical Motors, Brush, Victoria, Elwell-Parker, E.P.S., Siemens, Gramme, Gills, and Plating Dynamos; 4½in. Stroke Shaping, Horizontal Milling, Planing, Drilling, and other Machines; Fly Presses, Shafting; Six Hand Lathes, 4, 5, and 6in. Centres; 6½in. and 8½in. Slide Surfacing and Screw-cutting Lathes; 46 E.P.S. 23L Accumulator Cells in glass boxes; Switches, ½-H.P. Motors, Valuable Marble Standards, Electroliers, Brackets in brass and hammered-iron Canvas Belting, Loose Tools, Utensils, and other effects.

May be viewed on Monday, December 12th, 1892, and Morning of Sale.

For descriptive Catalogues and any further particulars apply to ARTHUR CLARKE, ESQ., Trustee, 6, Lombard-court, E.C., or to

CHEAP PREPAID ADVERTISEMENTS *relating to* **SITUATIONS VACANT AND WANTED, PLANT WANTED, FOR SALE, AND FOR EXCHANGE, &c.** *are inserted in "The Electrician," at the following low rates:*

Three Lines and Under ... ... **1s. 6d.**
Per Line After ... ... **6d.**

Nine Words to the Line

SITUATIONS VACANT AND WANTED, &c.

ASSISTANT ELECTRICAL ENGINEER WANTED. Write in first instance, and then call, stating experience and salary expected. IMPROVER WANTED. Also VACANCY for a PUPIL.—GILBERT & Co., 35, High-street, Kensington.

WANTED, First-class CANVASSER for Electric Light Business, to work on salary and commission; one who has had previous experience.—Write, stating experience and salary required, to "LUX," care of Everett and Son, 17, Royal Exchange.

ADVERTISER seeks SITUATION in Lighting Station or Private Installation; engine and machine repairs; 18 months' central station experience. Good references.—"Z.," 43, Langton-street, Chelsea.

AN ELECTRICAL ENGINEER who has had experience in installation work, desires SITUATION of similar capacity. Salary moderate. Good references.—Apply, "F. R.," 83, Downs Park-road, Clapton, N.E.

ELECTRICAL ENGINEER, just returned from abroad, seeks SITUATION. Has had theoretical training as well as 3 years' practical work, and 3 years' installing work. References and testimonials.—Apply by letter, to "L. C. I.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ELECTRICIAN requires RE-ENGAGEMENT on Private Installation or Central Station; thoroughly understands Engines, Dynamos and Accumulators, also repairs to same. First-class references.—Address, Box 1108, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

YOUNG ELECTRICAL ENGINEER, trained at Finsbury Technical College, desires CHANGE; experience in offices at central station, cable testing, &c.—"A. Z.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

Miscellaneous Advertisements, Plant Wanted and for Sale, &c., &c., continued on next page.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 760.—Vol. XXX. FRIDAY, DECEMBER 9, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6.

NOTES.

The experiments shown by Messrs. Rimington and Wythe-Smith at the last meeting of the Physical Society presented several features which are worthy of consideration by those who are interested in the nature of electricity. The displacement of the fan of images in Fig. 2 of the illustrations, which will be found in another column, and the relation between the number of these images and the speed, afford means for studying the effect of definite changes of potential on gaseous dielectrics; previous experiments with Tesla tubes having given only qualitative results. The closed ring of light, in an exhausted bulb, when surrounded with a few turns of a Leyden jar circuit, has been studied by Prof. J. J. Thomson, Prof. Elihu Thomson, and others; and while called "a discharge" by the former, and a "luminous band" by the latter (*Electrician*, Vol. XXVII., p. 296), the authors of the present Paper speak of "a circuit," and of "generating a current in such a circuit." After the meeting at the Physical Society a repetition of Prof. Elihu Thomson's experiment with an open coil of wire round a straight tube was tried, and a luminous spiral was plainly seen. The tube was filled with a pale glow, but there was no indication of a closed circuit. It is highly probable that if a straight wire were placed in contact with an exhausted bulb, a short and nearly straight luminous band would appear within it. The word "current," which is ever to be regretted, as fastening the material, if not the "single fluid" theory of electricity upon the science, is evidently unsuitable here, and if no synonym can be found for the term in everyday work, it might at all events be avoided in these cases.

Mr. Campbell Swinton has been engaged on some very interesting experiments on high frequency and high pressure discharges, using a modification of the simple apparatus employed by Prof. Elihu Thomson. He takes a current from the St. James' and Pall Mall Company, and using six 50 c.p. lamps in parallel running at a bright red, as a resistance, he works a powerful Apps coil, capable of giving a 10in. spark. Condensers are arranged in the usual way with the primary, and allow the contact breaker to work without heating or sparking. A short spark gap of about $\frac{1}{4}$in. is generally employed. Two Leyden jars are connected across the secondary circuit, which excites the primary of a simple induction coil immersed in oil. On a recent occasion we had an opportunity of seeing many of the Tesla and other brilliant experiments carried out with this apparatus, but one new effect of a peculiarly interesting character deserves special notice.

On placing the hand near one of the terminals of Mr. Campbell Swinton's coil, a few sparks shoot out from the brilliant violet brush discharge which envelopes them; the sensation is similar to that produced by short sparks from a Wimshurst machine. On approaching or touching a terminal with a piece of metal, or after grasping it, no sensation is felt. Mr. Swinton took an ordinary 5-candle 100-volt glow-lamp, and putting one terminal to earth through his body, presented the other to a terminal of the coil. At first the bulb became filled with a violet light, but on approaching, sparks shot into the terminal of the lamp, and the filament at once glowed to the extent of some two or three candle-power. A variation of the experiment is to connect one terminal of the lamp to earth by a wire, and to complete the circuit from one terminal of the coil to the lamp by the hands. A 32-candle 100-volt lamp was brought to full redness in the same way. If a complete circuit is not made, the bulb only glows.

At first sight it appears that about one-fifth of an ampere must pass in order to raise the filament to incandescence, and according to a common but extremely unscientific explanation the current becomes harmless because the frequency is high. Mr. Campbell Swinton, however, offers a very attractive theory and one which should be applied to all Teslaic and other high frequency experiments. He argues that by reason of the high frequency, the current is merely skin deep; the resistance is therefore high, since only a very small part of the filament acts as a conductor. The volts are high, and not easily measurable, and though the current is small, the watts spent on the filament are sufficient to raise it to incandescence. The lamp becomes, as he puts it, not a 100-volt lamp, but a 100,000-volt lamp. The whole of the high-frequency-and-therefore-harmless theory is thus completely exploded, and a most interesting, and, we believe, new hypothesis is put forward, and one which, if not original, is not likely to have been already "published" in some mathematical Paper. If any tolerable estimate of the fall of volts could be arrived at, the current which has hitherto defied all measurement might be deduced by photometric tests from the known watts per candle-power.

An able contribution to the subject of current curves has been made by Major Hippisley in a Paper printed in the

Hosted by Google

last number of the *Proceedings* of the Royal Society. The ordinary analytical method of determining the shape of these curves fails when the circuits possess iron cores, since the magnetism of the latter is not proportional to the current. The curves may be drawn by graphic methods if the connection between the magnetism and the current is known, and such processes have usually been resorted to when these curves have been obtained from theory. Major HIPPISLEY, however, has taken the **B H** curve, split it up into portions so that each part can be represented by analytical expressions, and has succeeded in obtaining the shape of the current curve after successive integration of the original current equation round the different portions of the **B H** curve. The method is difficult and lengthy, but it is interesting to find that the curves obtained by it compare fairly well with those obtained in other ways. Unfortunately, the author has taken the case of iron magnetised far beyond the saturation limit, a condition which, of course, does not exist in transformer cores and the curves are for this reason unlike those which actually represent the variation of the magnetising current of transformers. The effect of eddy currents in the core is also neglected. The curves, however, strikingly show the effect of hysteresis in disturbing their symmetry, and also bring out the effect of the extra currents which occur just after applying the alternating potential to the circuit.

A LARGE amount of work has been done during the last two or three years in connection with very rapid oscillations, but, since the experiments of BLASERNA and BERNSTEIN twenty years ago, little advance has been made in our knowledge of the comparatively slow oscillations occurring in circuits possessing ordinary amounts of inductance or capacity. It seems desirable just now that further experiments in this direction should be made, as Dr. FLEMING, in his Paper on Transformer Testing, read before the Institution of Electrical Engineers, has pointed out one or two cases in which the currents and potentials in ordinary alternate current circuits appear to be momentarily raised far above their normal amount, owing to the sudden closing or opening of a switch. An interesting communication by M. P. JANET on this subject will be found in another column. The student will find it profitable to compare these experimental curves with the theoretical ones worked out by Messrs. BEDELL and CREHORE, and given in *The Electrician* for November 4, 1892, p. 5. It remains for some skilled experimentalist to discover means for investigating the secondary current of an ordinary induction coil. Until this has been accomplished medical men must remain in ignorance as to the real character of that which they are pleased to call Faradic currents.

THE difference between a well-organised exhibition which supplies a long-felt want and one that no one needs is set forth in our Notes columns this week. The net outcome of the Edinburgh Exhibition of 1890 has been a call of nearly £27,000 upon the guarantors and a payment of 17s. 2d. in the pound to the creditors. At Frankfort subsidies have been repaid, and the exhibitors have received back about 5s. out of every pound paid for space.

IT is a matter of common knowledge, unsupported, we believe, by a single tittle of experimental evidence, that the worm will turn in the end, and that the last straw breaks the camel's back. Something of the kind appears to have happened to the Gas Light and Coke Company in connection with Col. HAYWOOD's thoughtful suggestion with regard to the City lighting. Glow-lamps indoors and arc-lights out of doors can be tolerated, says the gas Colossus, but combination gas and electric posts are things of naught. Seriously speaking, however, it was hardly to be expected that the gas people would fall in with the proposal that matters should be so arranged in the City alleys that gas could come to the rescue in the event of electricity failing. If the polite refusal of the Gas Company has the effect of putting the Electric Light Company on its mettle, and rendering breakdowns impossible, good will have come out of what was meant to be an evil.

THE moment the State undertakes commercial ventures things become mixed. The old Société Générale des Téléphones paid the Paris Municipality a handsome annual rental in return for being allowed to run its wires in the municipal subways. The Government, however, decline to follow this precedent, on the ground that since it has taken over the telephones, telephonic wires have been "translated," and are now *d'intérêt général*, and, therefore, exempt from taxation. The sum now owing to the Municipality looms large (in francs), amounting, as it does, to 737,000fr. A law suit is pending.

A CORRESPONDENT writes to us from New York to repudiate, on behalf of dynamo makers generally, the ironical criticisms which we recently reproduced from *Industries*. He fails to see the point of the remarks upon the extensive bed-plate, suitable enough for bolting to a rock, but ridiculous when hoisted on to two little slides. A planing machine is often occupied all day on the bottom of a bed-plate, which, after all, bears on four small surfaces; and yet we have only once seen a bed-plate designed to concentrate the weight on the slide rails. Our correspondent's argument for weight *versus* bolts is unsound, and is bad engineering. The eye-bolt seems to be a relic of the old Gramme and other dynamos. There were such strong temptations to lift them by rope slings round the upper magnet bars, that the provision of a convenient handle was imperative; but is this sufficient to account for its appearance on dynamos and on no other class of machinery?

Taunton.—The application of the Town Council for an Electric Lighting Order is to be inquired into by Sir T. W. P. Blomefield and Major Cardew, on Tuesday, the 13th inst.

Accrington.—The Town Council have decided to apply to the Local Government Board for sanction to borrow £10,000 for the establishment of an electric lighting central station.

Hertford.—The Town Council have resolved to put into operation the powers obtained more than a year ago, and to supply the electric current for public and private lighting.

The Durham College of Science.—On Monday last the Earl of Durham laid the foundation stone of a new wing of this College, and subsequently presented prizes to successful students.

Hosted by Google

Telephone Amalgamation.—The *Glasgow Herald* of Tuesday last gives currency to some further rumours regarding the amalgamation of the National and the New Telephone Companies.

Patent Record.—A Correction.—In reference to Patent No. 19,886 in the list of applications for patents given in our last issue, we are asked to say that the patent was applied for by W. Fuller, *Cambridge*, and not London, as stated.

Personal.—Major C. B. Waller, late manager and secretary of the London Electric Supply Corporation, has been elected to a seat on the Board, and Mr. R. Stuart Bain has been appointed secretary while still acting as acccountant.

City and Guilds of London Institute.—The prizes and certificates in connection with the above Institute will be distributed by Dr. W. Anderson at the Merchant Taylors' Hall, on Monday next, December 12th, at 7:30 p.m. The Lord Mayor will preside.

The American Philosophical Society.—This Society proposes to celebrate next year the 150th anniversary of its foundation. Meetings are to be held in Philadelphia May 22nd to 26th, at which Papers may be offered by such delegates as may honour the Society with their presence.

Royal Institution.—At the general monthly meeting of this Institution, on Monday last, Mr. Nikola Tesla was elected a member. The special thanks of the members were returned to Mr. Ludwig Mond for a donation to the fund for carrying on investigations on liquid oxygen.

Windsor.—We learn that the local Electric Lighting Company are proceeding with the work of laying their mains in spite of the fact that they expose themselves to penalties for so doing without having previously put themselves in order with regard to both the Board of Trade and the Town Council.

Cheltenham.—At the last meeting of the Town Council reports were presented by the Electric Lighting Committee covering 25 demy 8vo pages. Prof. Ayrton, adviser to the Corporation, recommended the adoption of the alternate current system. After a long discussion the meeting adjourned until January.

Stafford.—At the monthly meeting of the Town Council on Tuesday last the report of the Electric Lighting Committee was presented. It recommended the Council to take active steps for the provision of electric light for the borough. The cost of an installation of 3,000 lights would be £20,000. The report was adopted.

Worcester.—On Tuesday last the Watch Committee's recommendation to purchase the Powick Mills, and land adjoining, for £5,000, for the purpose of utilising the stream for generating electricity; and that the Council should enter into a contract with the Brush Company for carrying out the work for a sum not exceeding £23,109, was carried.

The Royal Commission on Coast Communication.—The Queen has by Warrant under Royal Sign Manual, dated November 26th, placed the name of Mr. W. H. Preece, in lieu of that of Mr. Edward Graves, deceased, upon the Royal Commission to inquire into the question of telegraphic communication with lighthouses and light-vessels around the coasts of the United Kingdom.

The Edinburgh Exhibition of 1890.—The Edinburgh Exhibition Association of 1890 has been dissolved by order of the Court. The liquidators' note stated that it had been necessary to call up the guarantee fund of £26,559. The total assets recovered amounted to £44,943, including £26,099 of the guarantee fund, and £10,966 for buildings. A total dividend of 17s. 2d. per pound had been paid to creditors.

Electrical Communication with Lightships.—Mr. Houghton, superintendent of the New York Maritime Exchange, is, says *Industries*, urging the Lighthouse Board to have the lightships and outlying lighthouses connected with the life-saving stations on shore by telegraph, telephone, or otherwise. It is stated that at the coming Session of Congress a Bill will be introduced appropriating a sum of £10,000 to cover the expense of the necessary experiments.

The Frankfort Exhibition of 1891.—The Managing Committee of this Exhibition recently issued its final financial statement. The total disbursements were £64,400, and the total receipts £69,200, thus leaving a balance profit of £4,800. Of this balance 15 per cent. was handed over to Herr Oscar von Miller, in accordance with his agreement; and the surplus was devoted to repaying subsidisers and exhibitors, the latter obtaining about 25 per cent. of the sums originally paid by them for space.

Cable Interruptions and Repairs:

	Interrupted.		Repaired.
Macao-Hong Kong	Nov. 29, 1892	.....	Dec. 3, 1892
Nagasaki-Shanghai.....	Dec. 2, 1892	.....	Dec. 8, 1892

THE FOLLOWING CABLES ARE ACTUALLY INTERRUPTED:

	Date of Interruption.
Bolama-Bissao (communication with)	September 9, 1892
Cayenne-Vizeu	September 24, 1892
Ceara-Maranham	November 9, 1892
St. Thomé-Loanda *	November 24, 1892
Penang-Medan.....	December 1, 1892

* Communication with South Africa is still maintained by the East Coast route.

The Marseilles Telephone Service.—The Marseilles telephone exchange was lately moved into a new building, and ever since the unfortunate subscribers have suffered severely, the lines, says *La Lumière Electrique*, being entirely unserviceable. In addition, the new multiple switchboard was found to be defective in several respects. A few days ago 300 subscribers held an indignation meeting, the upshot being the nomination of a committee with instructions to force on a telephone strike unless satisfactory assurances are forthcoming of better service in the immediate future, together with a reduction of rentals. The subscribers on strike are to abstain from using the telephone, and to refuse to pay for services *not* rendered.

Nottingham.—At the meeting of the Town Council on Monday last the electric lighting question came up for consideration. The Special Committee recommended that £44,755 should be expended on land, buildings, and plant in connection with a 10,000 light plant. Mr. H. Talbot, electrical engineer to the Corporation, recommended in his report to the committee the adoption of the three-wire system in combination with storage batteries and continuous current transformers. He also recommended the use, wherever possible, of bare copper conductors and culverts, the contractor to be required to keep them in a satisfactory condition for three years at his own expense. The Town Council deferred any discussion on the matter.

Birmingham.—At the last meeting of the Town Council the Mayor stated that, as to the question of electric lighting, the Committee had carefully considered the matter, and had come to the conclusion that at present there was not sufficient evidence to enable them to decide whether it was advisable that they should proceed to obtain a Provisional Order for the purpose of electric lighting in the city at large, and until they had been able to come to a conclusion on that point they did not think it desirable to allow any Company to obtain further rights for the city. They also desired that the electric light should be at the disposal of the inhabitants at an early date, but they considered that if they were to come to a premature conclusion now they might do that which would hamper the town for all time.

The City and South London Railway.—At the last meeting of the Lambeth Vestry the General Purposes Committee reported that the Railway Company had given notice of their intention to commence the construction of their extension to Clapham Common, authorised by the Act of 1890. The Committee recommended that all reasonable facilities should be given to the Company to carry out their work, as the Company would then be able to complete their works as soon as possible. A memorial was, however, read from residents near the Swan protesting against the Electric Railway Company being allowed to erect a hoarding there to the damage of local trade. Eventually, the Committee's recommendation, together with the memorial, was referred back to the Committee for further consideration.

Hosted by Google

The Telephone in Austria.—As previously stated in these columns, the Austrian Government will take over as from January 1st next the telephone exchanges in ten Austrian towns, now the property of the Telephone Company of Austria. The Government have decided to take over two additional towns since the last arrangement was reported, viz., Linz and Brünn, and negotiations are being carried on respecting the exchanges in Vienna, which, it is hoped, will result in an agreement placing the whole of the Austrian telephone system in the hands of the Government. Vienna possesses one single exchange, capable of serving 8,000 subscribers, all wires being underground. Up to the present time 6,500 subscribers are connected up, and the number of new subscribers averages from 150 to 200 per month.

Brighton.—At the meeting of the Town Council, on Thursday last week, the proposed extension of the electric lighting area in the town came up for discussion. Alderman Moon moved the adoption of the special reports of the Lighting and Works Committees, which together recommended an expenditure of £35,000. Mr. Arthur Wright presented a detailed account of the manner in which it was proposed to light the sea front, and also gave the estimated profits at the end of the first year's work as £108, in addition to £900 put by as a sinking fund. After a long discussion, the reports were adopted with only four dissentients. It is proposed to light the sea front by means of 40 arcs, to convert the Brighton system into a three-wire network, and to lay down additional engine, boiler, dynamo, and battery power.

Coventry and Electric Traction.—The General Works Committee of the Coventry Town Council have recently issued a report with regard to Mr. Graff Baker's proposed introduction of the overhead trolley system of electric traction into that town. A deputation visited Walsall and Leeds. The committee are of opinion that the poles and overhead wires would be such an obstruction, and would so much disfigure the streets of Coventry that they strongly advise that consent be refused to such a system in Coventry under any circumstances. Of the two systems, that at Walsall was by far the least objectionable. —— On Tuesday the report of the Committee was discussed with considerable heat, one member remarking, "If it was to be a question of steam or electricity with overhead wires then, by heavens, let them have electricity!" Ultimately the matter was adjourned.

A Monument to Gauss and Weber.—We have received a circular soliciting support on behalf of a scheme for erecting a monument in Göttingen to Charles Frederick Gauss and William Weber, world-renowned co-workers in the then but little explored field of electricity and magnetism. It is needless to say that this proposal to perpetuate the memory of the life's labours of Gauss and Weber deserves the ungrudging assistance of all physicists and especially of all electricians. The acting committee is composed of Prof. Klein, E. v. Meier (Curator of the University), F. Merkel (Pro-rector of the University), G. Merkel (Over-burgomaster), Profs. E. Riecke, E. Schering, W. Schur, W. Voigt, H. Weber, and S. Benfey (banker), and it is to the last-mentioned that subscriptions should be addressed (S. Benfey, Bankgeschäft, Göttingen). The list will remain open until April 1, 1893.

"The Electrician" Contributors' Dinner.—On Thursday evening last week a dinner was given at the Hotel Métropôle by the proprietors of *The Electrician* to past and present contributors. Sir John Pender presided, and, in addition to the proprietors and editorial staff, amongst those present were the Marquis of Tweeddale, Sir George Elliot, Mr. W. H. Preece, Prof. D. E. Hughes, M. Despecher, Mr. George Draper, Mr. H. C. Fischer, Mr. J. C. Lamb, Major Flood Page, Mr. John Muirhead, Mr. J. B. Verity, and other guests. Letters of regret were received at the last moment from Prof. Ayrton, Prof. Silvanus Thompson, Mr. Fletcher Moulton, Mr. Sydney Morse, Mr. J. Wilson Swan, Mr. Frank Bailey, and Mr. Shelford Bidwell. The contributors included Lord Kelvin, Lieutenant Bacon, R.N., Messrs. G. L. Addenbrooke, B. Blount, E. T. Carter, J. C. Chapman, C. W. S. Crawley, R. E. B. Crompton, Prof. J. A. Fleming, Prof. J. Perry, Messrs. W. Geipel, G. H. Robertson, H. A. Saunders, G. F. C. Searle, Dane Sinclair, A. T. Snell, Dr. W. E. Sumpner, Mr. J. Swinburne, &c.

The City Lighting.—At the meeting of the City Commissioners of Sewers on Tuesday, Colonel Haywood said he had applied to the Gas Light and Coke Company with regard to utilising the existing lamp-posts in the side streets for incandescent lights in such a way that if the electric light should fail the gas would still be available. The Company had replied, pointing out the difficulties under which they at present were carrying on the street lighting. They were being prosecuted by the City authorities for the impurity of the gas supplied to some of the lamps, which impurity was due to the presence of sulphuretted hydrogen owing to the stagnant gas in the disused gas pillars and pipes. Again, lamps were continually being lighted by unauthorised persons in consequence of the failure of the electric light, and by mischievous people passing on omnibuses. The Company thought the Commissioners would recognise the fact that they had done all in their power to facilitate the improved lighting of the streets even at considerable cost to themselves, and notwithstanding that the concessions made from time to time were in favour of an opposition mode of lighting. The Company could not allow their fittings to remain as suggested, but they proposed, as soon as the lamp-posts were utilised for the electric light, to vacate them altogether. The letter was referred to the Streets Committee.

Electricity in South African Gold Mines.—At the second ordinary general meeting of the shareholders in the Champ d'Or (Transvaal) French Gold Mining Company, on Friday last, the Chairman, Mr. E. Montfort, made the following interesting statement:—"Amongst other things, we might mention to you that we have been the pioneers of the introduction of electricity as a motive power for mines in the district. In the month of September last we introduced on our mine the first permanent plant for the electrical transmission of power, and since that time it has been running without stopping either night or day. Since its inauguration the plant has been increased, and now consists of two dynamos, driven from the mill countershafting, and connected by overhead copper wires to the motors at the reservoir, which is 700ft. from the mill. These motors drive the pumps and supply water for the whole mill. A starting switch at the mill allows the motor pump to be started, stopped, or regulated in speed, so that no attention is required at the motors or pumps. Thus a considerable saving of labour and wear and tear is effected. Previously the pumps had been driven by a wire rope, which was always giving trouble, and necessitated frequent stoppages of the mill for repairs, and it also wasted considerably more power. The estimated saving and gain from this source alone is reckoned at the rate of nearly £4,000 per annum."

Electric Lighting in Berlin.—The report of the Berliner Elektricitätswerke gives the following table, showing the consumption of current from its stations since its commencement in August, 1885:—

—	Private lighting (lamp-hours).	Street lighting.	Motors for factories (kilowatt-hours).
Aug.-Dec., 1885..	635,800	—	—
1886	5,052,024	50,890	—
1887-88, 1½ years.	11,932,000	104,682	—
1888-89	19,563,000	332,674	12,956
1889-90	41,850,000	361,052	69,591
1890-91	59,240,000	363,438	274,457
1891-92	80,524,000	361,808	186,611

The falling off in the item, "Motors for factories, &c.," is due to the fact that a large undertaking which formerly used the current has given up its factory in Berlin. The following figures refer to the total number of lights installed in Berlin:—

Date.	Arcs.	Glow lamps.
December 31, 1890	4,944	80,788
December 31, 1891	6,203	108,258

The increase in the number of lamps installed, taking arcs in proportion to their candle-power, is about 32 per cent. as against 29 per cent. last year. The increase in the consumption of gas during the same period was about 17 per cent.

ELECTROMAGNETIC THEORY.—XL.

BY OLIVER HEAVISIDE.

(*Continued from page 61.*)

§ 174. In the last paragraph I came dangerously near to overstepping the imposed limits of my treatment of vectors, which is meant to present the subject merely in the form it assumes in ordinary physical mathematics. If we were to ignore the physical applications, and treat vector algebra as a branch of pure mathematics, regardless of practical limitations, there would be no bounds to the investigation of the subject. It will now be convenient to wind up with a few remarks on the previous, and on the nature and prospects of vector analysis.

Since we live in a world of vectors, an algebra or language of vectors is a positive necessity. At the commencement of this chapter, §§ 97 to 102, I made some general remarks on the nature of cartesian analysis, vector analysis, and quaternions; and the reader is recommended to read them again from a more advanced point of view. Then, he was supposed to know next to nothing about vectors. Now, although he need not have absorbed all the special applications of vector algebra that have been given since, it may be presumed that he has acquired a general knowledge of the principles of the subject. There is no longer any question as to the desirability and utility of vectorial analysis. The present question is rather as to the form the vector algebra should take. On this point there is likely to be considerable difference of opinion, according to the point of view assumed, whether with regard to physical applications, or abstract mathematical theory. Let us then, to begin with, summarise the leading points in the algebra given above.

First, there is the idea of the vector as a distinct entity. Nearly everyone nowadays knows and appreciates the idea. And it is a noteworthy fact that ignorant men have long been in advance of the learned about vectors. Ignorant people, like Faraday, naturally think in vectors. They may know nothing of their formal manipulation, but if they think about vectors, they think of them *as* vectors, that is, directed magnitudes. No ignorant man could or would think about the three components of a vector separately, and disconnected from one another. That is a device of learned mathematicians, to enable them to evade vectors. The device is often useful, especially for calculating purposes, but for general purposes of reasoning the manipulation of the scalar components instead of the vector itself is entirely wrong.

In order to facilitate the reading of vector work, the vector has its special type, thus **E**. This Clarendon, or any very similar neat black type (not block letters), is meant to mark the vector, always the vector, and never anything else, with the obvious exception of headlines that speak for themselves. Also, to economise letters, and ease the strain on the memory, the same letter suitably modified serves for the tensor, the ort, and the three scalar components. Thus E is the tensor, or size, and $\mathbf{E}_1$ the ort (signifying the orientation) so that $\mathbf{E}=\mathrm{E}\mathbf{E}_1$; whilst the scalar components referred to rectangular axes are E_1, E_2, E_3. The physical dimensions may be most conveniently merged in the tensor E. Every vector has its species. The one we are most familiar with is the space vector, or straight line joining two points, or more strictly the displacement from one point to another. But all kinds of vector magnitudes are formally similar in having size and ort, and therefore, when considered vectorially, obey the same laws. The properties of the space vector therefore supply us with the rules or laws of vector algebra.

The addition and subtraction of vectors is embodied in the assertion (whose truth is obvious) that the sum of any number of vectors making (when put end to end) a circuit is zero; or, in another form, all the various paths by which we may pass from one point to another are vectorially equivalent, namely, to the vector straight from point to point. Every vector equation therefore expresses this fact. Every term is a vector; and if all the vectors be put on one side, with zero on the other, we express the circuital property; whilst if we have vectors on both sides of the equation, we assert the vectorial equivalence of two paths.

Any vector **A** and its reciprocal $\mathbf{A}^{-1}$ have the same ort, and their tensors are reciprocal to one another.

Coming next to combinations of vectors of the nature of products, we find they are of two kinds, scalar and vector. The scalar product of **E** and **F** is denoted by **EF**, and the vector product by V**EF**. Their tensors are $\mathrm{EF}\cos\theta$ and $\mathrm{EF}\sin\theta$ respectively, θ being the included angle. The scalar product is directionless; the ort of the vector product is that of the normal to the plane of **E** and **F**. The tensor and ort of V**EF** are $\mathrm{V}_0\mathbf{EF}$ and $\mathrm{V}_1\mathbf{EF}$.

The justification for the treatment of the scalar and vector products as fundamental ideas in vector algebra is to be found in the distributive property they possess, thus,

$$(\mathbf{a}+\mathbf{b}+\ldots)(\mathbf{c}+\mathbf{d}+\ldots)=\mathbf{ac}+\mathbf{ad}+\mathbf{bc}+\mathbf{bd}+\ldots, \quad . \quad (155)$$

$$\mathrm{V}(\mathbf{a}+\mathbf{b}+\ldots)(\mathbf{c}+\mathbf{d}+\ldots)=\mathrm{V}\mathbf{ac}+\mathrm{V}\mathbf{ad}+\mathrm{V}\mathbf{bc}+\mathrm{V}\mathbf{bd}+\ldots, \quad (156)$$

which hold good for any number of vectors. In the first equation the manipulation is as in common algebra, in all respects. In the second, in all respects save one; for the reversal of the order of the vectors in a vector product negatives it, thus, $\mathrm{V}\mathbf{ac}=-\mathrm{V}\mathbf{ca}$.

Here we have very complex relations of geometry brought down to elementary algebra. As Prof. Gibbs has remarked, the scalar and vector product, which consist of the cosine and sine of trigonometry combined with certain other simple notions, are "incomparably more amenable" to algebraical treatment than the sine and cosine themselves.

When we go on to combinations in threes, fours, &c., we find it is the same thing over again in various forms. Thus **c.ab** and **c**V**ab** and V**c**V**ab** define themselves by the above, being **ab** times **c**, and the scalar and vector products of **c** and V**ab** respectively.

Similarly with four vectors, as in **dc.ab**, the product of **dc** and **ab**; **dc.**V**ab**, which is **dc** times V**ab**; **d.c**V**ab**, which is **c**V**ab** times **d**; **d**V**c**V**ab** and V**d**V**c**V**ab**, which are the scalar and vector products of **d** and V**c**V**ab**; V**dc**V**ab** and VV**dc**V**ab**, which are the scalar and vector products of V**dc** and V**ab**. Combinations of two vectors are universal, and those of three are pretty frequent, but those of four are exceptional. But it should be noted that the scalar and vector product of two vectors are involved throughout, no new idea being introduced when more than two vectors are concerned.

When we pass on to analysis, we find just the same vector algebra to be involved. Vectors are differentiated with respect to scalars to make new vectors in the same way as scalars, and the ideas connected with differentials (infinitesimal) and differential coefficients are essentially the same for vectors as for scalars. We never require to differentiate a vector with respect to a vector, and there is a very good reason for it, because the operation is an indeterminate one.

The fictitious vector ∇ is omnipresent in tridimensional analysis. It only differs from a vector in being a differentiator as well, so that it follows vector rules combined with other functions. With it are associated the ideas of the slope of a scalar, and the divergence and curl of a vector, with corresponding important theorems relating to the transition from line to surface, and from surface to volume summations. The theory of potentials in its broad sense is also involved in the mathematics of ∇, including the relations, direct and inverse, of potential, slope, curl, and divergence.

As for the linear operator, that is only the scalar and vector product system again in a special form. Professor Gibbs's dyadic is a useful idea, and I have modified his notation to suit the rest.

It is neither necessary nor desirable that a student should know all that is sketched out above before he makes practical use of it. For vector analysis, like many other things, is best studied in the concrete application. The principles may be very concisely stated, being little more than explanations of the scalar and vector product, with some conventions about notation. A student might learn this by heart, and be little the better for it. He must sit down and work if he wants to assimilate it usefully. He may work with scalar products only to begin with, for quite a large ground is covered thereby. When familiarised with the working of vectors by practice so far as the scalar product goes, the further introduction of the

Hosted by Google

vector product will come comparatively easy. The former knowledge is fully utilised, and also receives a vast extension of application. For the vector product is a powerful engine, which, with its companion the scalar product, is fully capable of working elaborate mathematical analysis in a concise and systematic manner. The student need not trouble about linear operators at first. He will grow into them. It is far more important that he should understand the operation of ∇ as a vector, and its meaning in the space variation of functions.

§ 175. Now, a few words regarding Quaternions. It is known that Sir W. Rowan Hamilton discovered or invented a remarkable system of mathematics, and that since his death the quaternionic mantle has adorned the shoulders of Prof. Tait, who has repeatedly advocated the claims of Quaternions. Prof. Tait in particular emphasises its great power, simplicity, and perfect naturalness, on the one hand; and on the other tells the physicist that it is exactly what he wants for his physical purposes. It is also known that physicists, with great obstinacy, have been careful (generally speaking) to have nothing to do with Quaternions; and, what is equally remarkable, writers who take up the subject of vectors are (generally speaking) possessed of the idea that Quaternions is not exactly what they want, and so they go tinkering at it, trying to make it a little more intelligible, very much to the disgust of Prof. Tait, who would preserve the quaternionic stream pure and undefiled. Now, is Prof. Tait right, or are the defilers right? Opinions may differ. My own is that the answer all depends upon the point of view.

If we put aside practical application to physics, and look upon Quaternions entirely from the quaternionic point of view, then Prof. Tait is right, thoroughly right, and Quaternions furnishes a uniquely simple and natural way of treating *quaternions*. Observe the emphasis.

For consider what a quaternion is. It is the operator which turns one vector to another. For instance, we have

$$\mathbf{B} = \mathbf{A}.\mathbf{A}^{-1}\mathbf{B} + \mathbf{B} - \mathbf{A}^{-1}.\mathbf{AB}$$
$$= \mathbf{A}^{-1}\mathbf{B}.\mathbf{A} + \mathrm{V}\mathbf{A}\mathrm{V}\mathbf{B}\mathbf{A}^{-1},$$

identically. Or,

$$\mathbf{B} = (\mathbf{A}^{-1}\mathbf{B} + \mathrm{V}.\mathrm{V}\mathbf{A}^{-1}\mathbf{B})\mathbf{A}. \quad . \quad . \quad . \quad (157)$$

Here the operator in the brackets, say q, depends upon **A** and **B** in such a way that it turns **A** to **B**; thus, $\mathbf{B} = q\mathbf{A}$. It is a quaternion. It has a scalar and a vector part. The general type of a quaternion is

$$q = w + \mathrm{V}\mathbf{a}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (158)$$

where w is any scalar, and **a** is any vector. Since we know the laws of scalar and vector products we may readily deduce the laws of quaternions should we desire to do so. But we shall find that the above notation, though so well suited for vectors, is entirely unfitted for displaying the merits of quaternions. To do this we must follow Hamilton, and make the quaternion itself the master, and arrange the notation and conventions to suit it, regardless of the convenience of the vector and the scalar. The result is the singularly powerful algebra of Quaternions. To give a notion of its power and essential simplicity we may remark that the product of any number of quaternions, p, q, r, s, say, in the order named, is independent of the manner of association in that order. That is,

$$pqrs = p(qrs) = (pq)(rs) = (pqr)s. \quad . \quad . \quad (159)$$

This remarkable property is the foundation of the simplicity of the quaternionic algebra. It is uniquely simple. No algebra of vectors can ever match it, and Prof. Tait is quite right in his laudations from the quaternionic point of view.

But when Prof. Tait vaunts the perfect fitness and naturalness of quaternions for use by the physicist in his inquiries, I think that he is quite wrong. For there are some very serious drawbacks connected with quaternions, when applied to vectors. The quaternion is regarded as a complex of scalar and vector, and as the principles are made to suit the quaternion, the vector itself becomes a degraded quaternion, and behaves as a quaternion. That is, in a given equation, one vector may be a vector, and another be a quaternion. Or the same vector in one and the same equation, may be a vector in one place, and a quaternion (versor, or turner) in another. This amalgamation of the vectorial and quaternionic functions is very puzzling. You never know how things will turn out.

Again, the vector having to submit to the quaternion, leads to the extraordinary result that the square of every vector is a *negative* scalar. This is merely because it is true for quadrantal versors, and the vector has to follow suit. The reciprocal of a vector, too, goes the wrong way, merely to accommodate versors and quaternions.

And yet this topsyturvy system is earnestly and seriously recommended to physicists as being precisely what they want. Not a bit of it. They don't want it. They have said so by their silence. Common sense of the fitness of things revolts against the quaternionic doctrines about vectors. Nothing could be more unnatural.

Are they even convenient? Not to the physicist. He is very much concerned with vectors, but not at all, or at any rate scarcely at all, with quaternions. The vector algebra should satisfy his requirements, not those of the quaternion. Let the quaternion stand aside. The physicist wants, above all, to have clear ideas, and to him the double use of vectors, as vectors and versors, combined with unnatural properties of vectors to suit quaternions, is odious. Once a vector, always a vector, should be a cardinal axiom.

If the usual investigations of physical mathematics involved quaternions, then the physicist would no doubt have to use them. But they do not. If you translate physical investigations into vectorial language, you do not get quaternions; you get vector algebra instead. Even Prof. Tait's treatise teaches the same lesson, for in his physical applications the quaternion is hardly ever concerned. It is vector algebra, although expressed in the quaternionic notation.

Vectors should be treated vectorially. When this is done, the subject is much simplified, and we are permitted to arrange our notation to suit physical requirements. This is a very important matter. Most calculations are, and always will be, scalar calculations, that is, according to common algebra. The special extensions to tridimensional space involving vectors should therefore be done so as to harmonise with the scalar calculations, and so that only one way of thinking is required, instead of two discrepant ways, and so that mutual conversion of scalar and vector algebra is facilitated. The system which I expound I believe to represent what the physicist wants, at least to begin with. It is what I have been expounding, though rather by example than precept, since 1882. There is only one point where I feel inclined to accept a change, viz., to put a prefix before the scalar product, say Sab instead of **ab**, to balance Vab. Not that the S prefix is of any use in the algebra as I do it, but that mathematical writers on vectors seem to want to put the scalar and vector parts together to make a general or complete product, say $\mathrm{Q}\mathbf{ab} = \mathrm{S}\mathbf{ab} + \mathrm{V}\mathbf{ab}$. The function Q**ab**, however, does not occur in physical applications, which are concerned with the scalar and vector products separately. If I could omit the V as well as the S I would do so; but some sign is necessary, and the V of Hamilton is not very objectionable.

Gibbs denotes the scalar and vector products by $\alpha.\beta$ and $\alpha \times \beta$, using Greek letters. In my experience this is not a good way when worked out. It is hard to read, and is in serious conflict with the common use of dots and crosses in algebra, which use has to be given up. I use dots in their common meaning, either as multipliers or separators.

Prof. Macfarlane, who is the latest vectorial propagandist, denotes the scalar and vector products by cos **ab** and Sin **ab**. The trigonometrical origin is obvious. But, on this point, I would refer the reader to the equations (155) (156) above, and to the very trenchant remark of Prof. Gibbs which I have already quoted, as to the incomparably greater amenity of the scalar and vector product to algebraical treatment than the trigonometrical functions themselves. The inference is that vector algebra is far more simple and fundamental than trigonometry, and that it is a mistake to base vectorial notation upon that of a special application thereof of a more complicated nature. I should rather prefer sca **ab** and vec **ab**. Better still, Sab and Vab, with the understanding that the S may be dropped unless specially wanted.

Hosted by Google

Macfarlane has also a peculiar way of treating quaternions, about which I will express no opinion at present, being doubtful whether, if the use of quaternions is wanted, *the* quaternionic system should not be used, with, however, a distinction well preserved between the vector and the quaternion, by special type or otherwise.

I am in hopes that the Chapter which I now finish may serve as a stopgap till regular vectorial treatises come to be written suitable for physicists, based upon the vectorial treatment of vectors. The quaternionists want to throw away the "cartesian trammels," as they call them. This may do for quaternions, but with vectors would be a grave mistake. My system, so far from being inimical to the cartesian system of mathematics, is its very essence.

(To be continued.)

EXPERIMENTS ON SLOW ELECTRICAL OSCILLATIONS.

In a recent number of the *Comptes Rendus* appears an article by M. P. Janet, describing an investigation of the electrical oscillations occurring in conductors when the circuit, of which they form a part, is subjected to some sudden change.

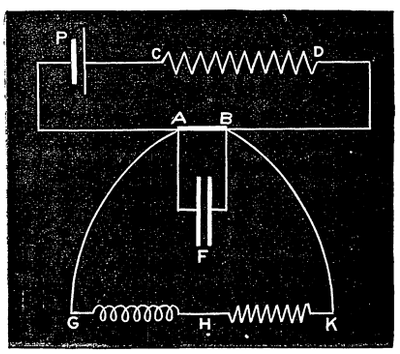

FIG. 1.

The arrangement of apparatus used by M. Janet is indicated in Fig. 1. A battery, P, was joined up in circuit with a high

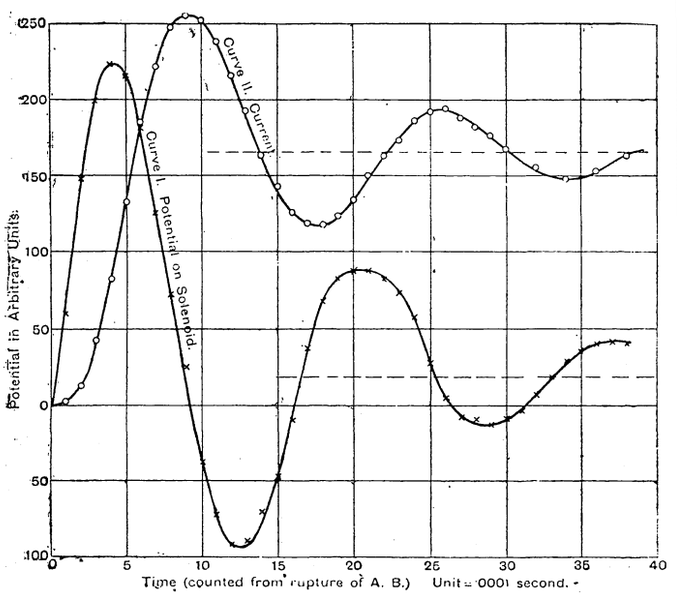

FIG. 2.

resistance of about 20,000 ohms between the points C and D, and also with a short-circuiting connector, A B. The points A B were connected with the terminals of a condenser, F, of about one-tenth of a microfarad, and also with a series combination of a solenoid, G H, and a non-inductive resistance, H K. The resistance of the solenoid was 228 ohms, and its self-induction 0·6 henry. The resistance of H K was 272 ohms.

When the short-circuit piece A B is removed, electric oscillations are set up in the circuits, and these have been investigated by M. Janet with the aid of a special contact maker, devised some years ago by M. Mouton, and used by him in his well-known induction researches. This apparatus is worked at a regular rate by a water motor, and makes two contacts periodically at an interval of time from each other, the amount of which can be adjusted at will. The first contact was arranged to remove the connector A B, and the second to connect the terminals of a condenser to two points of the circuit whose potential was under investigation. The charge of this condenser, measured subsequently in the usual way with a ballistic galvanometer, indicated the instantaneous value of the voltage existing between the points to which the condenser had been momentarily connected. The interval between the two contacts was varied in different experiments from 0·0001sec. to 0·0038sec., and the measured potentials (in arbitrary units) between the points G H and H K are plotted as ordinates in the curves shown in Fig. 2, the abscissæ denoting the time interval after the rupture of the contact A B. As the resistanee H K was non-inductive, the voltage between these points represents the current flowing in the conductor G H K. This current is represented by Curve II., the voltage on the solenoid being denoted by Curve I. The dotted lines represent the steady value attained by the potentials after the electrical oscillations have subsided. The curves show that the oscillations die out after about 0·004sec.

THE COST OF ELECTROLYTIC ALKALI AND BLEACH.

Seeing that the whole industrial importance of the numerous schemes that are now "in the air" for the production of alkali and bleach by electrolysis depends upon the cost of the products as compared with those manufactured by the older purely chemical processes, it is not a little significant that some mistiness has hitherto enveloped this most vital point. It is, therefore, with satisfaction that we welcome the estimate made by Messrs. Cross and Bevan, who have been intimately associated with this matter for some time past, and put forward in a Paper read by them before the London Section of the Society of Chemical Industry on December 5th. The figures which we are about to give, have, we understand, been derived from the data afforded by the working of the Le Sueur process on a scale of half a ton of bleach per day. The other method dealt with in the Paper was the Greenwood process, and in its description nothing novel to the readers of *The Electrician* was given, but its rival having been less freely brought into public notice, a short description of the peculiarities of the plant may not be superfluous. In the first place the diaphragm is horizontal, or nearly so, unlike that used by Greenwood, which is vertical, and below it is the cathode, which takes the form of an iron ring filled in with iron wire gauze. Although more nearly horizontal than vertical, and therefore justifying the distinction which we have drawn, the cathode has sufficient slope to facilitate the escape of the evolved hydrogen, which is always more or less a trouble in processes for the electrolysis of brine, and would be better suppressed if a good plan for so doing could be devised. The only other points claiming notice are the nature of the diaphragm, composed of parchment-paper, and asbestos, cemented together with coagulated blood albumen, and the anode, which is made of retort scurf, not cut to any regular size or shape, but used in rough rods fused into a leaden cap in the manner commonly adopted for making certain primary battery connections. Both the anode and the diaphragm are not claimed to be permanent parts of the plant upon which depreciation only has to be reckoned, as they need renewal every six or eight weeks and every 48 hours respectively.

Hosted by Google

The estimate of cost deals first with that of a horse-power hour, and in view of the considerable discussion as to what this really is or might be, we append the figures given by Messrs. Cross and Bevan. The plant is one of two engines of 1,200 I.H.P. each, and the cost per 24 hours is thus made up:—

Coal, 2·5lb. per horse-power hour, 64 tons at 10s.....	£32	0	0
Labour, 8 day men and 8 night men at 30s. per week.	4	0	0
Depreciation at 10% for 300 days per year—on engines £10,000, on boilers £7,000.....	5	14	0
Oil, waste, &c.	1	0	0
	£42	14	0

Therefore, this sum being the cost of 2,400 H.P. for 24 hours, the cost of 1 H.P.H. comes out at 0·178d., a result fairly concordant with Dr. John Hopkinson's estimate of one-third of a penny as the price at which Board of Trade unit should be produced.

The loss incurred in the conversion of mechanical into electrical energy and by leakage of current is taken as 17 per cent., so that 2,000 E.H.P. would be delivered at the terminals of the electrolysers. The pressure necessary for economical working is 4·5 volts, which is nearly double that which would be predicted from *a priori* considerations. This means a sacrifice of something like one-half of the possible amount of chemical decomposition, but with the internal resistance of the electrolytic cells as high as at present, it seems inevitable. In short, just as in the electrolytic refining of copper, either power must be wasted, or much capital locked up, and there is a certain intermediate position, varying with local conditions, that will be best to adopt. Reverting to the estimate, it is plain that 2,000 E.H.P. will provide 331,555 amperes at 4·5 volts, so that there are for the work of decomposition, 7,957,320 ampere-hours available in the day of 24 hours. As each ampere-hour is theoretically capable of producing 0·00292lb. of chlorine and 0·00331b. of caustic soda, it follows (taking an efficiency of 80 per cent.) that the output per day of 24 hours will be 8·3 tons of chlorine, equal to 22·43 tons of bleaching powder and 9·378 tons of caustic soda. The bleach, at the present selling price, £7. 10s. per ton, would be worth £168, and the caustic soda, reckoned at £12 per ton, £112. 10s., so that the total value would be £280. 10s. Having regard to the fact that in the Le Sueur process it is not proposed to turn out bleach but carbonate, by precipitating the liquor containing the caustic, with carbon dioxide, the value of the 12·428 tons of carbonate produced would be (at £5. 15s.) £71. 10s., and the total price of the products £239. 10s. The cost of production of these quantities may be arrived at from the figures given below:—

18 tons of salt at 12s.....		£10	16	0
12 tons of lime at 12s. ...		7	4	0
Power, 57,600 horse-power hours at one farthing		60	0	0
Labour		10	0	0
Casks and packages.....		18	0	0
Depreciation at 10 per cent. for 300 days on—				
Electrolysers	£12,000			
Dynamos	8,000			
Tanks, pumps, buildings.....	10,000			
	£30,000	10	0	0
Superintendence		1	0	0
General expenses.....		4	0	0
		£121	0	0

This does not include the cost of renewal of the diaphragms and anodes of the Le Sueur process, which is stated to reach what seems the extravagant sum of £30 per day, bringing the total cost of production up to £151, or £153, if the cost of carbonating the caustic liquor be taken into account.

Whatever may be thought of the items of this estimate, and some of them are, we conceive, debatable enough, it is at least the most serious and straightforward attempt that has yet been made to ascertain what is actually the margin of profit in electrolytic alkali making, using data that are of higher grade than those products of the imagination which so frequently adorn the pages of a prospectus, and have even been known to find their way into documents of less admittedly *ex parte* character

THE BOARD OF TRADE ELECTRICAL STANDARDS COMMITTEE.

SUPPLEMENTARY REPORT TO THE PRESIDENT OF THE BOARD OF TRADE.

Subsequently to the presentation of our former report* to Sir Michael Hicks-Beach in July, 1891, we were informed that it was probable that the German Government would shortly take steps to establish legal standards for use in connection with electrical supply, and that, with a view to secure complete agreement between the proposed standards in Germany and England, the Director of the Physico-Technical Imperial Institute at Berlin, Prof. Von Helmholtz, with certain of his assistants, proposed to visit England for the purpose of making exact comparisons between the units in use in the two countries, and of attending the meeting of the British Association which was to take place in August in Edinburgh. Having regard to the importance of this communication it appeared desirable that the Board of Trade should postpone the action recommended in our previous report until after Prof. Helmholtz's visit.

That visit took place early in August, and there was a very full discussion of the whole subject at the meeting of the British Association in Edinburgh, at which several of our number were present. The meeting was also attended by Dr. Guillaume, of the Bureau International des Poids et Mesures, and Prof. Carhart, of the University of Michigan, U.S.A., who were well qualified by their scientific attainments to represent the opinion of their respective countries. It appeared from the discussion that a few comparatively slight modifications of the resolutions included in our previous report would tend to secure international agreement. An extract from the report† of the Electrical Standards Committee of the British Association embodying the results of this discussion was communicated to us by the Secretary, and will be found in the Appendix to this report.

Having carefully reconsidered the whole question in view of this communication, and having received the report of the subcommittee mentioned in Resolution 14 of our previous report, we now desire, for the resolutions contained in that report, to substitute the following:—

Resolutions.

1. That it is desirable that new denominations of standards for the measurement of electricity should be made and approved by Her Majesty in Council as Board of Trade standards.

2. That the magnitudes of these standards should be determined on the electro-magnetic system of measurement with reference to the centimetre as unit of length, the gramme as unit of mass, and the second as unit of time, and that by the terms centimetre and gramme are meant the standards of those denominations deposited with the Board of Trade.

3. That the standard of electrical resistance should be denominated the ohm, and should have the value 1,000,000,000 in terms of the centimetre and second.

4. That the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice 14·4521 grammes in mass of a constant cross sectional area, and of a length of 106·3 centimetres may be adopted as one ohm.

5. That a material standard, constructed in solid metal, should be adopted as the standard ohm, and should from time to time be verified by comparison with a column of mercury of known dimensions.

6. That for the purpose of replacing the standard, if lost, destroyed, or damaged, and for ordinary use, a limited number of copies should be constructed, which should be periodically compared with the standard ohm.

7. That resistances constructed in solid metal should be adopted as Board of Trade standards for multiples and submultiples of the ohm.

8. That the value of the standard of resistance constructed by a Committee of the British Association for the Advancement of Science in the years 1863 and 1864, and known as the British Association unit, may be taken as 0·9866 of the ohm.

9. That the standard of electrical current should be denominated the ampere, and should have the value one-tenth (0·1) in terms of the centimetre, gramme, and second.

10. That an unvarying current which, when passed through a solution of nitrate of silver in water, in accordance with the specification attached to this report, deposits silver at the rate of 0·001118 of a gramme per second, may be taken as a current of one ampere.

11. That an alternating current of one ampere shall mean a current such that the square root of the time average of the square of its strength at each instant in amperes is unity.

* See *The Electrician*, Vol. XXVII., September 4, 1891, p. 491.

† This extract consists of four resolutions and some addenda, which were published in *The Electrician*, Vol. XXIX., August 26, 1892, p. 462.

Hosted by Google

12. That instruments constructed on the principle of the balance, in which by the proper disposition of the conductors, forces of attraction and repulsion are produced, which depend upon the amount of current passing, and are balanced by known weights, should be adopted as the Board of Trade standards for the measurement of current whether unvarying or alternating.

13. That the standard of electrical pressure should be denominated the volt, being the pressure which, if steadily applied to a conductor whose resistance is one ohm, will produce a current of one ampere.

14. That the electrical pressure at a temperature of 15°C. between the poles or electrodes of the voltaic cell known as Clark's cell, prepared in accordance with the specification attached to this report, may be taken as not differing from a pressure of 1·434 volts by more than one part in one thousand.

15. That an alternating pressure of one volt shall mean a pressure such that the square root of the time-average of the square of its value at each instant in volts is unity.

16. That instruments constructed on the principle of Lord Kelvin's quadrant electrometer used idiostatically, and, for high pressures, instruments on the principle of the balance, electrostatic forces being balanced against a known weight, should be adopted as Board of Trade standards for the measurement of pressure, whether unvarying or alternating.

November 29, 1892. (*Secretary*).

SPECIFICATION REFERRED TO IN RESOLUTION 10.

In the following specification the term silver voltameter means the arrangement of apparatus by means of which an electric current is passed through a solution of nitrate of silver in water. The silver voltameter measures the total electrical quantity which has passed during the time of the experiment, and by noting this time the time average of the current, or if the current has been kept constant, the current itself can be deduced.

In employing the silver volatmeter to measure currents of about one ampere the following arrangements should be adopted. The kathode on which the silver is to be deposited should take the form of a platinum bowl not less than 10 cm. in diameter, and from 4 to 5 cm. in depth. The anode should be a plate of pure silver some 30 sq. cm. in area, and 2 or 3 mm. in thickness. This is supported horizontally in the liquid near the top of the solution by a platinum wire passed through holes in the plate at opposite corners. To prevent the disintegrated silver which is formed on the anode from falling on to the kathode, the anode should be wrapped round with pure filter paper, secured at the back with sealing wax. The liquid should consist of a neutral solution of pure silver nitrate, containing about 15 parts by weight of the nitrate to 85 parts of water.

The resistance of the voltameter changes somewhat as the current passes. To prevent these changes having too great an effect on the current, some resistance besides that of the voltameter should be inserted in the circuit. The total metallic resistance of the circuit should not be less than 10 ohms.

Method of Making a Measurement.

The platinum bowl is washed with nitric acid and distilled water, dried by heat, and then left to cool in a desiccator. When thoroughly dry it is weighed carefully. It is nearly filled with the solution, and connected to the rest of the circuit by being placed on a clean copper support to which a binding screw is attached. This copper support must be insulated. The anode is then immersed in the solution so as to be well covered by it and supported in that position; the connections to the rest of the circuit are made. Contact is made at the key, noting the time of contact. The current is allowed to pass for not less than half an hour, and the time at which contact is broken is observed. Care must be taken that the clock used is keeping correct time during this interval. The solution is now removed from the bowl, and the deposit is washed with distilled water, and left to soak for at least six hours. It is then rinsed successively with distilled water and absolute alcohol, and dried in a hot air bath at a temperature of about 160°C. After cooling in a desiccator, it is weighed again. The gain in weight gives the silver deposited.

To find the current in amperes, this weight, expressed in grammes, must be divided by the number of seconds during which the current has been passed, and by 0·00118. The result will be the time-average of the current, if during the interval the current has varied.

In determining by this method the constant of an instrument the current should be kept as nearly constant as possible, and the readings of the instrument taken at frequent observed intervals of time. These observations give a curve from which the reading corresponding to the mean current (time-average of the current) can be found. The current, as calculated by the voltameter, corresponds to this reading.

SPECIFICATION REFERRED TO IN RESOLUTION 14.

Definition of the Cell.

The cell consists of zinc and mercury in a saturated solution of zinc sulphate and mercurous sulphate in water, prepared with mercurous sulphate in excess, and is conveniently contained in a cylindrical glass vessel.

Preparation of the Materials.

1. *The Mercury.*—To secure purity it should be first treated with acid in the usual manner, and subsequently distilled in vacuo.

2. *The Zinc.*—Take a portion of a rod of pure redistilled zinc, solder to one end a piece of copper wire, clean the whole with glass paper, carefully removing any loose pieces of the zinc. Just before making up the cell dip the zinc into dilute sulphuric acid, wash with distilled water, and dry with a clean cloth or filter paper.

3. *The Zinc Sulphate Solution.*—Prepare a saturated solution of pure ("pure re-crystallised") zinc sulphate by mixing in a flask distilled water with nearly twice its weight of crystals of pure zinc sulphate, and adding zinc oxide in the proportion of about 2 per cent. by weight of the zinc sulphate crystals to neutralise any free acid.* The crystals should be dissolved with the aid of gentle heat, but the temperature to which the solution is raised should not exceed 30°C. Mercurous sulphate treated as described in 4 should be added in the proportion of about 12 per cent. by weight of the zinc sulphate crystals, and the solution filtered, while still warm, into a stock bottle. Crystals should form as it cools.

4. *The Mercurous Sulphate.*—Take mercurous sulphate, purchased as pure, and wash it thoroughly with cold distilled water by agitation in a bottle; drain off the water, and repeat the process at least twice.* After the last washing drain off as much of the water as possible. Mix the washed mercurous sulphate with the zinc sulphate solution, adding sufficient crystals of zinc sulphate from the stock bottle to ensure saturation, and a small quantity of pure mercury. Shake these up well together to form a paste of the consistence of cream. Heat the paste, but not above a temperature of 30°C. Keep the paste for an hour at this temperature, agitating it from time to time; then allow it to cool; continue to shake it occasionally while it is cooling. Crystals of zinc sulphate should then be distinctly visible, and should be distributed throughout the mass; if this is not the case, add more crystals from the stock bottle, and repeat the whole process. This method ensures the formation of a saturated solution of zinc and mercurous sulphates in water. Contact is made with the mercury by means of a platinum wire about No. 22 gauge. This is protected from contact with the other materials of the cell by being sealed into a glass tube. The ends of the wire project from the ends of the tube; one end forms the terminal, the other end and a portion of the glass tube dip into the mercury.

To set up the Cell.

The cell may conveniently be set up in a small test tube of about 2 cm. diameter, and 6 or 7 cm. deep. Place the mercury in the bottom of this tube, filling it to a depth of, say, 1·5cm. Cut a cork about 0·5cm. thick to fit the tube; at one side of the cork bore a hole through which the zinc rod can pass tightly; at the other side bore another hole for the glass tube which

* See Notes.

Hosted by Google

covers the platinum wire; at the edge of the cork cut a nick through which the air can pass when the cork is pushed into the tube. Wash the cork thoroughly with warm water, and leave it to soak in water for some hours before use. Pass the zinc rod about 1cm. through the cork.

Clean the glass tube and platinum wire carefully, then heat the exposed end of the platinum red hot, and insert it in the mercury in the test tube, taking care that the whole of the exposed platinum is covered. Shake up the paste and introduce it without contact with the upper part of the walls of the test tube, filling the tube above the mercury to a depth of rather more than 2cm. Then insert the cork and zinc rod, passing the glass tube through the hole prepared for it. Push the cork gently down until its lower surface is nearly in contact with the liquid. The air will thus be nearly all expelled, and the cell should be left in this condition for at least 24 hours before sealing, which should be done as follows :—

Melt some marine glue until it is fluid enough to pour by its own weight, and pour it into the test tube above the cork, using sufficient to cover completely the zinc and soldering. The glass tube should project above the top of the marine glue.

The cell thus set up may be mounted in any desirable manner. It is convenient to arrange the mounting so that the cell may be immersed in a water bath up to the level of, say, the upper surface of the cork. Its temperature can then be determined more accurately than is possible when the cell is in air. In using the cell sudden variations of temperature should, as far as possible, be avoided.

Notes.

The Zinc Sulphate Solution.—The object to be attained is the preparation of a neutral solution of pure zinc sulphate saturated with $ZnSO_4$, $7\,H_2O$. At temperatures above 30°C. the zinc sulphate may crystallise out in another form; to avoid this 30°C. should be the upper limit of temperature. At this temperature water will dissolve about 1·9 times its weight of the crystals. If any of the crystals put in remain undissolved they will be removed by the filtration.

The amount of zinc oxide required depends on the acidity of the solution, but 2 per cent. will, in all cases which will arise in practice with reasonably good zinc sulphate, be ample. Another rule would be to add the zinc oxide gradually until the solution became slightly milky. The solution when put into the cell should not contain any free zinc oxide; if it does then, when mixed with the mercurous sulphate, zinc sulphate and mercurous oxide are formed; the latter may be deposited on the zinc and affect the electromotive force of the cell. The difficulty is avoided by adding, as described, about 12 per cent. of mercurous sulphate before filtration; this is more than sufficient to combine with the whole of the zinc oxide originally put in, if it all remains free; the mercurous oxide formed together with any undissolved mercurous sulphate is removed by the filtration.

The Mercurous Sulphate.—The treatment of the mercurous sulphate has for its object the removal of any mercuric sulphate which is often present as an impurity. Mercuric sulphate decomposes in the presence of water into an acid and a basic sulphate. The latter is a yellow substance—turpeth mineral—practically insoluble in water; its presence at any rate in moderate quantities has no effect on the cell. If, however, it is formed the acid sulphate is formed also. This is soluble in water, and the acid produced affects the electromotive force. The object of the washings is to dissolve and remove this acid sulphate, and for this purpose the three washings described in the specification will in nearly all cases suffice. If, however, a great deal of the turpeth mineral is formed it shows that there is a great deal of the acid sulphate present, and it will then be wiser to obtain a fresh sample of mercurous sulphate rather than to try by repeated washings to get rid of all the acid. The free mercury helps in the process of removing the acid, for the acid mercuric sulphate attacks it, forming mercurous sulphate and acid which is washed away.

The cell may be sealed in a more permanent manner by coating the marine glue, when it is set, with a solution of sodium silicate and leaving it to harden.

PHYSICAL SOCIETY.

At a meeting of the Physical Society on November 25, 1892, the following Paper was read :—

"Experiments in Electric and Magnetic Fields, Constant and Varying."

By E. C. Rimington and Wythe Smith.

The object the authors have in bringing these phenomena before the Society is not to establish any new theory, nor to show imperfections in present theories, but to exhibit experiments which help the actions, taking place in a dielectric under stress, to be more easily grasped.

The experiments are divided into two sets :—(1) Performed in varying electric fields. (2) Performed in varying magnetic fields. Although these two fields cannot exist separately, their effects are isolated.

Set 1.—*Constant Electric Field.*

A constant electric field was produced by two charged metal discs + and −, each of which was struck on the outside of a glass plate (Fig. 1). The object of the glass plates was to prevent brush discharges between objects placed in the field and the plates.

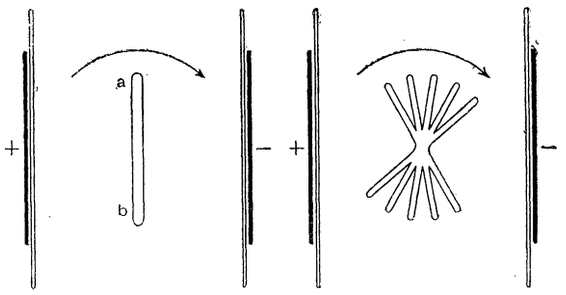

Fig. 1.

Fig. 2.

Fig. 1, *a*, *b* represents a partially exhausted electrodeless tube, placed in the uniform electric field. In the position shown, the tube is at a uniform potential. Now let it rotate in the direction of the arrow; the potential of *a* will fall, and *b* rise until the potential difference between the ends is sufficient to break down the tubes. There will then be a displacement current equalising the potential, during the continuance of which the tube will glow. On rotating still further a similar action will take place. The effect of these actions is to produce a double fan-shaped set of images, as shown in Fig. 2. The number of images in the fan depends on the intensity of the field. This phenomenon is intensified by constricting the middle part of the tube.

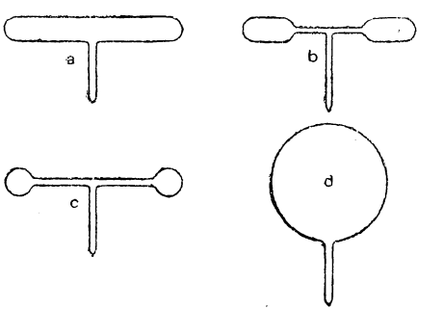

Fig. 3.

In designing the tubes for these experiments, care was taken to have the point where they were connected to the pump in such a position that there was no tendency for discharge to take place at these points when in use. The tubes used in this experiment are shown in Fig. 3 (*a*, *b*, *c*, and *d*). The stem was used to connect them to the whirling motor. The surfaces of these tubes should be fairly clean and dry, and it is advisable with a new tube, or one left unused for some time, to excite it between the knobs of an influence machine. In the double fan-shaped set of images one end will be seen to be brighter than the other, the current passing from the dull end to the bright end. Not only is this effect visible with a straight tube, but on rotating an exhausted bulb in the field a stationary luminous region will be seen.

Varying Electric Field.

Instead of rotating the tube a similar effect is produced by varying the field in which the tube is placed. The tube should be

Hosted by Google

placed with its longer axis in the direction of the lines of force. The plates in this case may either be charged and discharged by influence-machine and dischargers, the latter sparking, or by an induction-coil, with or without sparking. When an induction-coil is used, very long tubes will glow when brought near.

SET 2.—*Magnetic Field.*

The authors were of the opinion that, by taking advantage of the action of the Geissler tube, one might show Hertzian phenomena to fairly large audiences. They therefore substituted a Geissler tube for the spark-gap in the resonator. This was very successful with a Leyden-jar oscillator. The oscillator and resonator consisted of two similar small Leyden jars for capacity, and a single convolution of thick copper wire for the conductor-circuit. The Geissler tube was placed as a shunt to part of the conductor-circuit of the resonator (*see* Fig. 4).

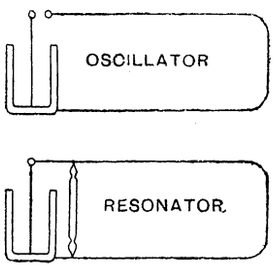

FIG. 4.

But although they designed special tubes, they were unable to get good results with the ordinary forms of Hertz oscillator and resonator. They next made a resonator of the following form :— Two metal plates, *a* and *b* (Fig. 5), give capacity, and the wire self-induction. An electrodeless exhausted tube was placed as dielectric between the plates. When a fairly large Hertz oscillator was used, this tube glowed brightly, even when taken to considerable distances.

Glow Produced in Varying Magnetic Fields.

Instead of, as in the last set of experiments, having a secondary composed partly of a metallic conductor and partly vacuum-tube, the whole circuit may be composed of rarefied gas. It is evident that, in order to generate a current in such a circuit, a large induced E.M.F. would be required ; this would have necessitated either a very strong magnetic field, or one which changed very rapidly. The former was out of the question, the latter was obtained by taking abvantage of the phenomenon of oscillatory discharge in the following manner :—

P (Fig. 6), a primary consisting of a very few turns of gutta-percha covered wire, was placed in a Leyden-jar circuit, as shown. As a secondary an exhausted bulb, or annular tube, was placed near P. On sparks passing at D, a bright ring of light appeared in the scondary. In the actual experiments a metallic secondary, S, was also wound with P and exactly similar to it. On short-circuiting S, the induced current in this circuit will weaken the magnetic field so as to completely extinguish the Geissler secondary.

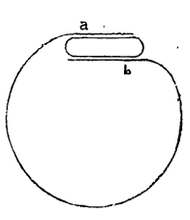

FIG. 5.

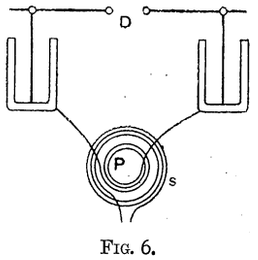

FIG. 6.

If S is connected to a third coil, this coil will behave in a similar manner to P, with weaker effects ; P and S in this case form a one to one transformer. The wire of the coil P is itself luminous when S is open ; short-circuiting S will stop this effect.

(Since the authors started their researches some of these latter experiments have been shown by Prof. Thomson.)

DISCUSSION.

Mr. SWINBURNE thought some of the effects shown were not Hertzian, but merely cases of ordinary mutual induction. He inquired whether the vacuum tubes would still glow if the Leyden jars were removed from the so-called resonating circuits. He was also of opinion that in the magnetic experiments the surfaces of the bulbs, and not the enclosed gases, took the charges.

Mr. WATSON asked if the authors had tried screening off the long waves by a wet cloth. If the effects still existed, this would prove that they were Hertzian.

Mr. BLAKESLEY wished to know if the images of the rotating tubes were at equal angular distances.

Mr. SMITH pointed out that these distances were not equal, but corresponded to equal changes of potential.

Prof. AYRTON remarked that the only cases where the materials of the bulbs, tubes, &c., did not influence the results were those in which discharges were produced by varying magnetic fields.

Mr. E. T. CARTER thought an induction coil a more efficient machine for producing the glow in tubes than the alternator, &c., used by Mr. Tesla.

Prof. S. P. THOMPSON said he first noticed that sparks passed between pieces of metal in the vicinity of an induction coil, sparking into a condenser in 1876, when he was showing some experiments on telegraphic apparatus before the Society ; but unfortunately he did not pursue the subject. Long before Mr. Tesla's investigations, Dr. Bottomley had shown that exhausted tubes could be caused to glow ; but it was not until Tesla produced such phenomena on a large scale that people recognised how much light could be got in that way.

Mr. RIMINGTON, in replying, said that the explanation why, in the experiments performed in varying magnetic fields, the bright parts of the luminous discharges were near the wire, appeared to be, that the E.M.F. was greatest in these places. Although he had not tried the experiment, suggested by Mr. Swinburne, of taking off the Leyden jar, he felt sure that doing so would stop the glow.

HUMAN DYNAMICS ; OR THE STUDY OF MOTIVE AND CHARACTER.

On Wednesday evening last week, at the Finsbury Technical College, Mr. Ll. B. Atkinson, A.M.I.C.E., delivered his presidential address to the Old Students' Association. Mr. Esson, Past-President, briefly introduced the new President, who delivered the following address :—

It is now about ten years ago since I used to attend in this lecture hall as a student of the Technical College, and I had very little suspicion then that it would ever fall to my lot to stand up in the same room, I will not say as a professor, but, at all events, as a lecturer. I have had some little difficulty in deciding what subject I should bring before you, but I have arrived at the conclusion that the best thing to do would be to give you some of the ideas that have occurred to me since I left the College with regard to the success or the failure of technical education, and in what way I think it might be improved in the future.

I.—First of all, what are the objects and scope of technical education as at present understood : let us consider for a moment the history of technical education. For a great many years, of course, science has been known in all its varied aspects, and we have had science taught and studied at the Universities, and at various colleges, and science has been also largely studied by amateurs, using the word amateurs in the sense of people who study science simply for its own sake. It has been studied simply as dealing with the methods and laws of nature, and never going any further than finding out what those laws are and learning them ; that in fact is *pure science.* The stage comes, however, when people begin to find out that, by studying these laws of nature, they can really do more than record the facts, that is to say, they find that they can make use of them, that they can learn to *control* nature by studying the laws of nature, and control her to their advantage. It was discovered, however, that the persons who had studied science in the way that it was then taught did not, for some reason or other, seem to be in a position to apply science to practical life—to make any use of it. It is notorious that nearly all modern improvements—the improvements, in fact, by which the nineteenth century had been marked, improvements of a material nature depending on scientific facts—have not been made by scientific men. It is true, for example, that the safety lamp in one form was invented by Davy, but it is also true that it was disputed whether he or George Stephenson, the pitman, really first discovered the principle. The inventors of the steam engine—the early inventors, certainly—had very little scientific knowledge in the sense that they had studied science and deliberately set to work to apply the laws they had discovered to the use of man. For this reason, therefore, it has been thought wise to start schools and colleges of *technical* education, in which science would be taught with the direct object of applying it to the use of man, by controlling the forces of nature for his benefit, and it was doubtless with that object that this college and the other colleges in London and the country have been formed. A very great deal has now been done in the direction of teaching science in its useful aspect, and all old students of this college recognise I supposed personally what has been done for them in that direction. Still there remains one thing more. I have spoken of *pure science,* and of *technical science,* but, after all, science is no use, unfortunately or fortunately, in the present day unless we regard its *commercial aspect.* "Can a scientific problem be made to pay?" That is the question we have to face at every turn. It is no use for us to devise ingenious and clever contrivances, chemical processes, electrical processes, or mechanical arrangements, unless by

Hosted by Google

them we can supplant something already existing, and this can only be done if the new scheme shows a lower rate of cost. That I take to be the *commercial* side of technical education, and that appears to me to be the side of technical education which is overlooked in the technical education which I went through, and there are many I think, who were with me at that time who felt the same. It so happens that in the course of a year I see a very large number of students who have passed satisfactorily through various courses at different colleges, and as far as scientific knowledge and technical and practical knowledge is concerned, are all that could be desired. On the other hand, I know that when they apply for situations or posts, they are met with the question whether they have had any *practical experience.* Taking the industry with which I am connected, electrical engineering, so far as practical experience went, I frankly admit that the majority of these students have practical experience, in the sense that they can carry out almost any experimental work, and knew everything that was or ought to be done, say with electrical machines or instruments, very nearly as well as those who have been in the trade a very long time. The nature of the courses at this college, and of the tests, with apparatus at their disposal, with regard to machinery and engines, enables the students to know very nearly as much in some cases as they would if they had been in a works for two years; but what they do lack in the way of practical experience is that they are utterly ignorant of the fact that they have to do the work in a way to make it pay. In dealing with it as a matter of cost, what they wanted to know is, how is cost to be kept down? what are the differences in operating machinery that occasioned expense? what is it, in fact, that is entailed by what is broadly termed *management?* It is at this point—and I base my opinion on the observation of a large number of students—that technical education fails. Students do not realise the fact that scientific work must be done so as to make it pay. What they have to learn is not only that scien e means controlling *matter*, but that commercial science means controlling *human agents* also, and it is this element of human agency that is entirely neglected in all technical education, so far as I am aware. It is an element of the very greatest importance, because, after all, commercial scientific processes are carried on through a human agent or agents, such as managers, foremen and workmen. The question arises, is it impossible to teach what I will call this practical experience (and by practical experience, I mean the relation of men and women to the scientific operations that have to be carried out) in a college. It seems to me that technical education at the present time tends to produce a race of inventors, people who are always devising some brilliant scheme, but who forget the element of cost. It is notorious that inventors do not often succeed in making money out of their inventions, the idea goes into the hands of somebody else who makes the money, while they have the trouble of making the invention. I believe that this can be overcome to a very large extent by treating human agency, or, as I prefer to call it, *human dynamics* as a scientific subject, just as we treat mechanics, electricity or hydrostatics as a scientific subject. For instance, to teach mechanics we have a class in which all the laws of mechanics are laid down and shown, and, as far as they can be, proved on the black board; the student then passes into the laboratory, and in a few hours convinced himself that in the main the facts stated are correct. He does not go into the laboratory to find out for himself every law of mechanics. Why should not the same apply to human dynamics? I do not say that every fact in connection with experience of men can be taught in a class-room, but the laws that are likely to hold good can be so taught, and the student might be left to a short laboratory class in the laboratory of the world to satisfy himself of the truth of those laws, to find out to what extent they are correct. This course would put a student when he left a college much more in a position to deal with men as well as with matter than under the present system. I am aware that by suggesting this I may perhaps bring upon myself a charge which used to be considered one of great gravity, that of treating men from a very materialistic point of view, but, after all, we either directly or indirectly admit that men are controlled by some kind of laws, as are other things in the world of nature. In this case there is a greater uncertainty about the results of these laws, because it is much more difficult to find out the causes, and we have to endeavour to be in a position, with a few points in an orbit of comparatively unknown form, to predict the rest of the path—in other words to form an opinion as to what any man will do under any given circumstance. When a student leaves a technical college he has a very fair idea as to what stress can be put upon a steel wire without breaking it, or as to when it will break, but very few students when they leave have the slightest idea as to what inducements or temptations a man may be subjected before he will rob his employer. I believe that to some extent the one can be predicted in the same way as the other, if we take the trouble to find out the connection between cause and effect. We may, if we like, deal with the matter from a point of view that is very common in these class-rooms, draw a curve of human progress; that curve if it was simply in two dimensions—though I think it would have to be in n dimensions to make it really complete—may represent any one motive in a man's life; and taking a series of curves we may show what at any period in a man's life would be the effect of a given motive on his character, what action would result. If we take the *slope* of that curve, its differential coefficient in mathematical terms, it will represent the rate at which a man was improving or the reverse. If we take the area contained between the curve and its ordinates that area will practically represent what his habits are, because it will represent the summation of the various motives and actions which have operated on his character up to that date. What are really the simpler elements in the consideration of human dynamics, I think they may be taken in this way. Most people have some specific tendencies, or marked points in their character; everybody also has certain motives from time to time acting upon them, and the result of these two quantities is that we get a third quantity, a definite line of action.

Let us briefly consider what line such a study of human dynamics will take. The ordinary educationalist in dealing with youth begins with the assumption that all youth is naturally vicious and bad, and that all grown up people when they reach a certain age are perfection; and that duty of the educationalist is in the meantime to keep the youth under control till he arrived at the stage of perfection. Of course we know that this is all humbug, and that the fact is that people of all ages have certain vices and virtues, weaknesses and fads, and so on, and the aim, at all events, of the educationalist at a technical college would be to point out these virtues and vices, these strong and weak points in men's characters; how they have to be dealt with; how they can be made use of; and how they can be avoided, in relation to their use in the workshop of the world. The independent quantities that I would suggest for such teaching are *motive, character,* and *action,* corresponding in mechanics to force, mass, and motion, or corresponding in electricity to electromotive-force, resistance, and current. To bring the subject within the lines of a scientific argument, I suppose it will be said that we ought to have units of measurement of these quantities. I am afraid in the present state of the science however, so far as I am aware such units are not in existence. I may suggest the possibility of making measurements in some units; for instance, any youth knows that he ought not to burn a letter which was the property of somebody else, even if it was of no advantage to himself to have it burnt. Let us find out as our measurement the number of shillings which it would be necessary to give that youth to break down the barrier and get him to burn the letter. This would be a very simple problem. A rather more complicated one would be to find out how many shillings must be offered to a youth to persuade him to rob an orchard; there we have to consider whether the youth does or does not like sour apples, and his knowledge of the probability of the owner catching him in the act. I admit that all such considerations would make the system a complicated one, and I am not prepared this evening to lay down any units of measurement. How, then, are we to get at the result we want, namely, to find out the motive which is acting at any moment on a man, and to find out his character, and what he will do under given circumstances? To answer that we must consider what are, broadly speaking, the motives that weigh with people. Of course, first of all, there are what may be termed the animal motives, that exist even in a savage, such as *hunger, desire for comfort, love, self-preservation,* those are motives which affect every man and every race. As the scale of civilisation advances we come to *mental* and *moral motives,* such as *esteem* and *respect for others, pride* of name or family—which is often a very strong motive—*ambition,* and *desire for fame.* Then there are religious motives, and also what are termed altruistic motives. Religious motives may be really animal, being, in fact, simply the desire to avoid or gain certain pains or benefits which any particular religion happens to indicate. Altruistic motives, in a sense, are really selfishness in its highest form, where the desire to please others whom we may not even know is greater than the desire to please ourselves; but still, after all, it is an endeavour to put the highest personal pleasure as the point to be aimed at. Napoleon summed up all motives in two very short ones: he said that all men were governed either by self-interest or fear; he had heard that there was another motive—love, but this, he said, he had discovered to be an infatuation, and merely temporary. I do not think we can bring motives into quite so narrow limits as that; but the fact remains that the motives which move people to action are really very limited. You will have noticed that I have left the question of money as a motive out of question, the reason being that money, strictly speaking, is only a motive of action as being exchangeable for some of the other motives I have mentioned. There are a few people in the world called misers, with whom money itself is an object, but they are very rare, and are not often found, I suppose, under fifty years of age. Of all these motives, what I have termed the animal motives are the most general; they exist practically everywhere, and must always be counted upon. The mental and moral motives, and the religious motives that I have indicated, vary enormously, and are very much more complicated, and it is more difficult to decide whether and to what extent they exist; in fact, they can only be found out by a careful study of individuals in a manner which I will presently indicate briefly. So much for what might be termed the impressed forces in our law of motion. The second thing we have to deal with is character. Character, of course, strictly speaking, in the English language is a mental department, and I think we ought, therefore, to combine with character temperament, because what we have to deal with is the action of a motive, not only on the mental organisation, but on the physical organisation, or temperament. We must never forget the importance of dealing with the physical as well as the mental aspect of this question. Two men may be of exactly similar mental characteristics, but what they would do in a particular circumstance will depend very largely on their physical organisation; whether to one man it will be physical trouble or not to do a certain thing, often completes the balance of action. For instance, there might be two men of equally hot temper, whom we will suppose to have been insulted; the one, of small physical organisation, would probably take it quietly, where the other, of a large and powerful organisation, would probably knock his insulter down. At all events, those would be the two directions in which I should expect the action to take place in the two cases. Seeing that human motive and human temperament are so complicated a subject, how are we to find out what are the elements in the problem? First of all, I think we cannot neglect the influence of heredity, taking it not only in its personal aspect as regards the family or group of families, but also as regards a race or nation. There are various expressions in the English language which indicate that this is partly recognised by people. We hear people speak of a man as a "thorough Jones," meaning that all the Joneses act in a certain manner under certain circumstances; or we hear the expression, "a regular Englishman," which means that under particular circumstances Englishmen act in a particular way. We know what it is when a man

Hosted by Google

acts as a "typical Scotchman." These expressions really indicate that people, without thinking of it, have studied human dynamics, and summed up certain types and characteristic, on which they base their opinion as to what a man will do under certain circumstances.

Let us consider for a moment some of the results of a study of human dynamics. The men who have made the greatest successes in the government of men in every instance have been those who have made a study of motives and character, with a view of predicting beforehand the action which the men they chose for certain posts would take. It used to be said of Napoleon —who was a great student of character—that he never chose a man for a general who had not large nostrils, whatever his other merits might be ; the reason was that he thereby estimated that the man was of a large physical and lung capacity, and could therefore stay in the saddle for a long time without suffering exhaustion, and thereby was capable of leading his armies under the very great stress of circumstances in which they were often placed. In that example—which I believe to be a true fact—we see how necessary it is to consider not only the mental, but the physical character of a man selected for special objects. If we look through the history of men of business, men who have founded colonies, who have organised railway systems, men of every class who have had to carry out work which they could not carry out entirely themselves, we find that the success of these men has been due to their choosing the right men to do the work they wanted doing. Probably each of these men worked, so far as his study of human dynamics was concerned, on lines of his own, and found out by experience certain rules which he thought would guide him, and which he relied upon. It is a fact of common knowledge which can be denied by none, that the choice of the right man for the right place has made the success of most of the leaders of the great departures of the nineteenth century ; indeed, it is hardly an exaggeration to say that the greatest discovery of the nineteenth century is the discovery or the production of a race of natural organisers, instinctive choosers of men to properly fill any given post. Now, in my view, a Technical College should take cognisance of this fact in its teaching. The whole success in the management of men in carrying out scientific and industrial operations consists in not trying to teach people to do things which they are not intended by Nature to do, but in selecting such people as are intended by Nature, or are suitable for carrying out any particular operation, to carry it out. I have spoken of the independent quantities leading to action, of *motive* and *character*. I have tried to impress on you the importance of a knowledge of these ; it remains to consider how we may discover these quantities. A little earlier on I mentioned the integral or summation of character and action in the general term habit. Now, to find out a man's character we really have to differentiate his habits with respect to time and motive. This may appear speaking in an involved manner ; what I want to express is this : if you want to know what a man will do, see what he has done before, what he is doing now. That is the whole secret. Every movement a man makes, every glance of the eye, how his hair grows on his head, the shape of his jaw, how he carries his head, every wrinkle on his face, his hands, how he wears his clothes, and what clothes he wears, how he writes, how he speaks—these and more are really habits, are indelible records of what he has done before, of what he will do again. It is in the study of these records that the integral quantity in human dynamics, the sum of actions, is to be found ; differentiate it with respect to one motive, and character remains, combine character with a fresh motive and action can be calculated. Some success has been attained in some branches of the subject in reducing them in some degree to a scientific basis. Darwin has made a study of the "expression of the emotions," which he reduces simply to the question of what muscular movements are involved in the expression of different emotions ; and these movements, if reproduced continually, leave their marks in permanent lines in the features of a man. If a man, for instance, is constantly engaged in deep and abstruse thought you will invariably find him with contracted eyebrows, and certain lines in the forehead between them, the reason being, as Darwin has shown, that in carrying out abstruse thought we naturally draw back the eyes and contract the eyebrows. If, therefore, we want to employ a man to carry out abstruse considerations we should never employ a man with a perfectly smooth face, indicating that he does not habitually contract his eyebrows in thought, for such contractions cannot be made without leaving their marks. That in its broad lines forms the science of physiognomy—the study of the face of a man as the record of his character, and the motives and actions which have gone beforehand. We may, in fact, say that men of certain features have certain characteristics. I maintain that it may easily be taught what those features and characteristics are—what a man with one set of features will do under particular circumstances, and what a man with a different set of features will do. These are things that may be taught in a class-room, and which everybody may verify for himself practically as he goes about the world. Phrenologists also have attained some considerable success in indicating the characteristics, character, and capabilities of men from an examination of the shape of their heads. In handwriting, again, I think that everybody, by taking a little trouble, may have a very large guide to character. I have recently had placed before me about 200 letters from applicants for an important post that I might give my opinion as to which I thought the most suitable man. I selected one of the letters, partly from the handwriting and partly from the style of the letter, though there was very little information in it. There was a great sorting out of these applicants, and finally seven or eight of the most suitable were brought up to London and interviewed by a board of directors. The result was that they selected the man whom I had selected from his handwriting, though I had not told them the name. That might perhaps be attributed to a lucky shot, but I am convinced of the great advantage of the study of handwriting in relation to character, the results of which can be applied to the selection of people to carry out any particular class of work. A great deal might be done before students started in their professions if there were a professor of human dynamics to tell them what they were likely to be successful with, and what they were not likely to be successful with. I was struck very much the other day when I happened to be in the Law Courts how every barrister in the room had one marked set of features ; there were none who differed from this in any large degree. The meaning of that was that the men who went into the profession who had not that class of countenance were not successful, and dropped out, and it might have been told them years before, at the beginning of their studies instead of at the end, that they would never make a success at the Bar. This subject of human dynamics is a subject which, quite apart from the class-room, we may all study. I find myself, the moment I get into a railway-carriage, speculating as to what every man in the carriage is, what is his profession, and what his errand, and I assure you that after a little study one could guess these things very closely. I find myself also, when asking anybody a question, rapidly predicting the answer, in words sometimes, and you would be surprised to know how very often the nature and the direction of the reply can be told. It really brings the matter down to the stage almost of being an amusing game. Where in whist, for instance, you play for a trick simply on the merits of the trick, without any consideration of what has gone before, the game is not worth playing ; but if you consider it in relation to all that has gone before, and all that your partner has had or is likely to have in his hand, whist is a very interesting game. So it is in dealing with people : if in asking a man a particular question, you look to what has gone before, and to the man's character, and endeavour to forecast his reply, there is an additional interest. It may be said that if a man is guided by rigid rules, and will almost invariably act in a particular direction under certain circumstances, that this seems to deprive him of the attribute of free will. Without going so far as that, it may be distinctly stated, I think, that there are certain people who have in certain directions no free will whatever. That is to say, if they attempt to do things for which they are not naturally adapted they *must* fail. It is not a question simply of whether they do or do not choose to try to succeed ; they cannot succeed, and if that can be determined before they waste time in trying, a great advantage will be gained. It is impossible within the limits of a short address to go deeply into a question like this, and I have only suggested various lines of thought that have occurred to me, and which, I may say, have been of considerable practical value to me ; and if I have succeeded in turning the attention of others in the same directions, I shall be satisfied.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, December 9th.

PHYSICAL SOCIETY.

5 p.m. Ordinary Meeting. Papers to be read :—(1) "On Colour Vision," by W. B. Croft ; (2) "On Japanese Magic Mirrors," by Prof. S. P. Thompson ; (3) "Reflection from Diffusing Surfaces," by Dr. Sumpner.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read :—"Electric Light Cables," by E. S. Franklin.

MONDAY, December 12th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture. I., 4, "The Generation of Light from Coal Gas," by Prof. Vivian B. Lewes.

TUESDAY, December 13th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed :—(1) "The Manufacture of Small Arms," by John Rigby, M.A. ; (2) Paper to be read, time permitting :—"Gas Power for Electric Lighting," by J. Emerson Dowson, M.Inst.C.E.

CHEMICAL SOCIETY.

8 p.m. Extra Meeting on the anniversary of the death of Jean Servais Stas.

WEDNESDAY, December 14th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read :—"The Utilisation of Niagara." By Prof. George Forbes, F.R.S.

THURSDAY, December 15th.

CHEMICAL SOCIETY.

8 p.m. Ballot for the Election of Fellows. Papers to be read.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.

7:30 p.m. Paper to be read :—"Continuous Current Dynamos," by J. Brentnall Duckett.

FRIDAY, December 16th.

OLD STUDENTS' ASSOCIATION.

8 p.m. Smoking Concert at Broad-street Station Restaurant.

*** Particulars of meetings to be held or Papers to be read before Scentific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Hosted by Google

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.* "THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.		6 months.		12 months.	
	s.	d.	s.	d.	s.	d.
For the United Kingdom	5	0	10	0	19	6
For Foreign Parts and Colonies :—						
Within Postal Union	6	6	12	6	24	0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Phillippine Islands, Siam, Transvaal, and Zanzibar	7	6	14	6	28	0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. [*Nearly ready.*

DRUM ARMATURE WINDING, AND COMMUTATORS: In Theory and Practice. By F. M. WEYMOUTH. [*Nearly ready.*

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRICITY AS A MOTIVE POWER. By A. T. SNELL. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price : Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

FULL CATALOGUE : POST FREE ON APPLICATION.

ELECTRICAL STANDARDS.

With the presentation of a supplementary Report to the President of the Board of Trade, the labours of the Committee on Electrical Standards may be assumed to have ended. The real work had been finished some time ago; it consisted, firstly, in the careful discussion of both principles and details, and secondly in the construction and calibration of the concrete standards. The delay in further proceedings has been due to international civilities. The opportunity for giving and receiving a reciprocal acknowledgment, offered by the proposal of the German Government to establish legal standards, was not to be missed. The discussion was re-opened at Edinburgh, and but slight modifications in the original Report were found necessary to secure agreement. The only change in the numerics is that of 1·434 instead of 1·433 as the voltage of a Clark's cell at 15°C. A very complete set of instructions for making and setting up this cell has been appended to the Report, which will be found elsewhere in our present issue. The instructions for using the silver voltameter are much more brief, but this matters less; not, indeed, because the operation is less difficult to carry out with four-figure accuracy, but because no one need ever perform it for measuring current or for calibrating instruments.

An intelligent man visited the British Museum the other day and asked to see "the original Sanskrit." The library authorities were rather puzzled, and, after some questions, found that the inquirer had been interested in an article on philology, and was endeavouring to carry out the instructions given in a foot-note—"See the original Sanskrit in the British Museum." Anyone impelled by curiosity, or animated by scientific inquiry, if he be also armed with the

Hosted by Google

requisite authority, may inspect one of the original Yards, and may gaze on that mass of platinum which was, until recently, the original Pound, but which, having been tried in the balance and found wanting, leaves us at present with no Imperial Standard of Mass. Similarly, the standard ohm may be seen, and standard Clark cells may be inspected; but the standard ampere, unlike any other unit, is represented only by a balance and coils of wire on a marble cylinder.

The work of the Standards Committee has, on the whole, been accomplished with just that degree of scientific accuracy which is most likely to command respect. The ohm might have been defined as a velocity; Clause 13 might have contained allusions to polarisation and magnetic fields. On the other hand, the "bot" was rejected and the ambiguity of the alternating ampere was allowed to pass. A subsequent attempt was made to bestow a name on the supply unit, but failed, owing to lack of a real demand. The dilemma let loose upon the Committee by Mr. H. E. Harrison still lurks among the mysteries of alternating currents, nor is it likely to give any trouble until the practice of redressing alternating into continuous currents becomes more common. Proposed by Mr. Ferranti, Sir David Salomons, and others, and actually carried out in practice by M. Leblanc, such rectification may be sometimes convenient, but presents the anomaly that 1·11 alternating ampere, as defined by the advisers to the Board of Trade, is required to produce one of the straightforward variety. We have admitted that this may be sometimes convenient, but why not turn continous currents into alternating by a dynamotor? The advantage of this would be an efficiency of 110 per cent., quite enough to float a company on, in these bad times.

OBITUARY.

WERNER VON SIEMENS.

It is with deep regret that we have to record the death in Berlin on Tuesday, of Dr. Werner von Siemens, founder of the famous firm of Siemens and Halske, and Chairman of Messrs. Siemens Bros. and Co., of London, Dr. Siemens died in the evening at half-past six, after a few days' illness. On Tuesday next he would have celebrated his 76th birthday. He was some time ago attacked with influenza, which brought on inflammation of the lungs, and the doctors declared that, considering his great age and his weakened condition, his recovery was not probable. In Dr. Werner von Siemens the scientific world loses one of its most widely known representatives. It is a curious coincidence that Dr. Siemens fell ill on the very day on which his Reminiscences were published.

Born at Lenthe, in Hanover, in 1816, and educated at the Lübeck Gymnasium, Dr. Siemens joined the Prussian Artillery in 1834, where his eminent talents soon attracted notice. Whilst in the army he applied himself with great zeal to the study of practical chemistry and physical sciences, and became the inventor of the process of electro-gilding, the differential governor, and the electric automatic recording telegraph, for all of which patents were granted him in Prussia.

In the autumn of 1840 his studies were interrupted by a somewhat curious incident. He acted as second in a duel, and was sentenced to five years' confinement in a fortress. He was sent to the citadel of Magdeburg. But even there he continued his experiments by setting up a small laboratory in his cell. A Magdeburg jeweller bought his rights in connection with electro-plating for 40 louis d'or. This gave him the means of further experiments, when, unexpectedly, after one month's imprisonment, he was pardoned. His request to be allowed to remain a little while longer in his cell in order to complete his experimental work was regarded by the authorities as an impertinence, and he was summarily expelled from prison at midnight.

As member of a Commission of the Prussian General Staff for the introduction of the electric telegraph system in place of the optical telegraphs, he proposed, in 1847, the application of subterranean conductors, insulated by gutta-percha, and successfully carried out experimental lines coated with gutta-percha by means of a press invented by him for that purpose, which is still used in the manufacture of cables. With the help of these insulated wires he succeeded in laying, together with Prof. Himly, the first submarine mines with electric ignition in the spring of 1848, for the protection of the harbour of Kiel from the Danish fleet. In the same year he carried out the first great telegraph line in Germany between Berlin and Frankfort-on-the-Main, and in the following year the subterranean line between Berlin and Cologne.

Dr. Siemens left Government service in 1850, and devoted himself afterwards entirely to scientific studies and private enterprises. Dr. Siemens' personal achievements are to be found in the field of science as well as in that of the technical arts. His scientific merits induced the University of Berlin to confer on him the dignity of Doctor of Philosophy, *honoris causâ*, in 1860; they opened likewise for him the doors of the Academy of Sciences in Berlin in 1874, and subsequently of many other academies and societies. In 1892 he was elected an Hon. Member of the Institution of Civil Engineers, and he was Hon. Secretary of the Institution of Electrical Engineers for Germany. Amongst his many and various claims to renown, and to the gratitude of mankind, must be mentioned the invention and practical application of the mercury unit (Siemens' unit); the gutta-percha press already referred to; the development of methods for testing underground and submarine cables, and determining the position of faults; polarised relays; the Siemens armature, the dynamo, the principle of which he published at a meeting of the Berlin Academy of Sciences, on January 17, 1867; the electric railway, and numerous other inventions, such as the pneumatic despatch tube system.

Dr. Siemens was a member of the Prussian Order "Pour le Mérite," and the late Emperor Frederick III. of Germany conferred upon him the patent of nobility. In 1886 Dr. Siemens laid science under a deep obligation by presenting 500,000 marks to the German nation for the foundation of a national scientific and technical institution.

INSTITUTION OF ELECTRICAL ENGINEERS.

At the annual general meeting of the Institution of Electrical Engineers, held last night, the following members of Council were elected for the year 1893:—

President.

W. H. Preece, F.R.S.

Vice-Presidents.

Alexander Siemens.	Sir David Salomons, Bart., M.A.
R. E. Crompton, M.Inst.C.E.	Sir Henry Mance, C.I.E., M.Inst.C.E.

Members of Council remaining in Office.

Major G. W. Addison, R.E.	Prof. A. B. W. Kennedy, F.R.S., M.Inst.C.E.
Prof. J. A. Fleming, M.A., D.Sc.	W. M. Mordey.
Prof. Geo. Forbes, F.R.SS. (L. & E.)	Prof. John Perry, D.Sc., F.R.S.
Edward Hopkinson, M.A., D.Sc.	James Swinburne.
Colonel R. Raynsford Jackson.	

New Members of Council.

Frank Bailey.	Gisbert Kapp, M.Inst.C.E.
Walter T. Goolden, M.A.	

Associate Members of Council.

W. A. Chamen.	Arthur Wright.
C. P. Sparks.	

Honorary Treasurer.

Sir David Salomons, Bart., M.A. (*Vice-President*).

It was announced in the course of the reading of the annual report that the Institution Premium had been awarded to Mr. Nikola Tesla for his Paper, "Experiments with Alternate Currents of High Potential and High Frequency"; the Paris Electrical Exhibition Premium being awarded to Mr. Anthony Reckenzaun for his Paper, "Load Diagrams and the Cost of Electric Traction"; and the Fahie Premium to Messrs. Heaviside and Jackson for their Paper, "Electrical Distribution by the Newcastle-upon-Tyne Electric Supply Company."

SPARKING AT COMMUTATORS.

BY F. M. WEYMOUTH.

Few inventions probably, in connection with the industries of modern times, have produced so many unexpected results as the dynamo. Of these, moreover, the causes have often for a long time eluded research, and have remained incomprehensible, leading to much perplexity and a great amount of working in the dark. While the most puzzling effect is doubtlessly the sparking that takes place at the brushes and the commutator.

It is far however, from being a matter of mere scientific interest to find out what may be the precise cause or causes of this peculiar phenomenon. For, as seen from a practical, not to say a mercantile standpoint, these scintillations, so brilliant to the eye, are none the less a manifestation of so much wasted energy, destruction of material, and loss in capital or dividends. A double object, therefore, each of weight, will attend any investigation into such a subject; and it is hence, with this purpose in view, that we may now proceed.

At the outset of our task various preliminary questions occur, which will have presented themselves in times past, and doubtlessly still present themselves to the inquiring mind in detail. Thus, what are the exact reasons that brushes will spark in one position on a commutator and not another; and why worse in one position than another? Why do some dynamos always spark, but not others? Or, again, why do dynamos sometimes spark, and yet at other times give no trouble in this direction whatever? While a yet further problem of some present day interest relates to the comparative absence of sparking in connection with the use of carbon brushes.

For the better solution of these and many other similar queries, it will thus be well if, in the first instance, we endeavour to attain some clear understanding on the subject of electric sparking generally, apart from that in connection with commutators in particular. We should, perhaps, need to be excused if in so doing we run over ground which is already more or less covered in various text-books. But our apology must be that to omit this elementary matter would be to leave out some most important links in the general chain of our argument; while it is evident that, without a proper comprehension of the fundamental laws and facts, no really good and satisfactory understanding of more complex portions of the subject ultimately to be arrived at, will be possible.

A first necessary condition for any sparks is that there be a difference of potential or electric pressure between two bodies for a spark to pass from one to the other; and such a spark will then flash from the body of higher potential to the lower.

It will now, however, afford assistance in the elucidation of our subject as a whole if we submit electric sparks to a subdivision into five distinct orders. These are as follows:—

(1.) Statical disruptive sparks.
(2.) Induction disruptive sparks.
(3.) Self-induction disruptive sparks.
(4.) Continuous flame, or voltaic arc.
(5.) Continuous disruptive discharge.

The above classification, it may thus be observed, is based on differences partly in the effects, and partly in the causes. We may briefly review these orders separately, before more fully studying them in a greater or less measure conjointly.

The first is distinguished by the fact that it occurs with statical electricity: that is, the electricity which is produced by friction between various substances, such as glass and silk or fur, and resides on the surface of the charged bodies. Two bodies thus charged respectively with positive and negative electricity, or one of them not charged at all, being brought near together, a disruptive spark will flash between them without their being in contact.

A spark of the second class takes place in connection with current electricity, such as is generated by a chemical battery or a dynamo. It is of high voltage and disruptive, and like the first, requires no previous contact of the objects between which it passes.

The third, or self-induction spark, is also the result of current electricity, and a high electromotive force between the terminals. It is likewise disruptive, but only follows after previous contact.

The fourth in our classification, or voltaic arc, is a further phenomenon in connection with current electricity. It is preceded by a spark of the third order; but is then dependent on the electrodes not being parted by too great a gap in proportion to the strength of the current and its potential, principally the latter. This latter condition being observed, it has the peculiarity that it continues over a gap too great for the normal potential to send a spark across, in the well-known manner exemplified by the ordinary arc lamp, and contrariwise to the complete cessation of their being, and the infinitesimally small fraction of time occupied by a spark of either the first three orders.

The continuous discharge forming our fifth order is a simple effect in current electricity, where there is a normal very high potential difference between the electrodes. It is disruptive, and requires no previous contact.

We may now, however, subject the above to a more complete analysis, taking the various orders into consideration, not only separately, but as intimated, also in conjunction with one another. Thus, statical electricity, besides residing on the surface for instance of jars or brass knobs and so forth, is of extremely high potential, it may be of hundreds or thousands of volts; while the current, if it may be said to have any in passing from one object to another, may only be a minute fraction of an ampere. A peculiarity, moreover, of sparks of this class, even when of great length, and so of great potential, is that they have but little effect on the electrodes they play between, such as the brass knobs of a frictional electrical machine, which only become slightly tarnished. But they are far however from being necessarily harmless: for these sparks have this further peculiarity, that they are destructive to any dielectric substance that may be between the electrodes, in the sense that they can *pierce* or *break* and *rupture* any such object. Thus a spark may be made to pierce not only the *air*, but with a sufficiently high potential difference between the electrodes, also glass, paraffined wood, ebonite, or other such materials. Hence the term "disruptive," as applied to this kind of spark. It is in this direction, indeed, that the destructive effect of lighting is probably to be found. For while a cloud may be a body heavily charged with statical electricity, say positive, the true negative will be the damp interior of the earth. Objects projecting above the ground, such as trees and tall chimneys and so forth, are for the most part dielectric, though perhaps not entirely so, especially in so far as they contain moisture; but in so far as they are dielectric, the large disruptive spark known as a "flash of lightning" has a destructive effect on them in its endeavour to pass by their means to its true negative in the body of the earth; while a good conductor, such as a copper rod extending from the summit of the erection down well into the earth, will not encounter the disruptive qualities of the discharge, and so will escape damage.

Passing the second and third of our orders for the time being in this more particular review, we may now glance at our fourth order—the arc. As a clear conception of the production and continued generation of this form of electrical flame will tend to a good understanding of our subject as a whole, we may consider it with more or less thoroughness. In the first instance it has to be borne in mind that the carbons in an arc lamp form, part of what is termed a "circuit." That is, the electric current, starting from some generator, is conveyed by a conductor, say, a copper wire, to one carbon; it thence passes to the other carbon, and back by another conducting wire to the negative terminal of the generator. In this case moreover, at least with "continuous" currents, the electricity passes through the *interior* of the conductor, in contradistinction to the manner of the statical electricity, which lies on the surface. With the latter, a "circuit" as above described, is not necessary; for there it is a pure case of two bodies charged at different potentials, of which when they are brought sufficiently near, or are connected, the one higher charged will discharge into the lower one, so that both become of equal potential. This may be likened to the case of two tanks of water at different levels; when connected by a pipe the water in the higher

Hosted by Google

one will flow into the lower till both are of the same level. But there is nothing of the nature of a circuit; and when the water in both is of the same level, the action ceases. Current electricity, on the other hand, may be compared to the case of hydraulic distribution of power, wherewith the water is pumped by engines into a series of pipes which convey it to various points where its energy may be utilised, as for working lifts and hoists, and thence bring it back to the suction of the pumps once more. It *may* be brought back to the pumps, that is. For after having been used, it can be run to waste, or returned to the earth instead, and fresh water be pumped into the pipes. The *earth* may then be said to be the return half of the water circuit. For as the used up water is returned *to* the earth, so is the fresh water drawn originally *from* the earth. It is thus also with electric currents, though it practice only with weak currents, such as are used for telegraphing purposes. The return half of the circuit may be the earth instead of another wire or "lead."

Reverting however to the arc, we find the explanation of this phenomenon, which we take from Prof. Silvanus Thompson's "Elementary Lessons in Electricity and Magnetism" (though we use our own words), to be as follows:—On the carbons being duly connected up in a circuit as described, they are first allowed to be in contact at their points. A current, which experience shows should not be less than 5 amperes as a minimum, or at a less pressure than 40 or

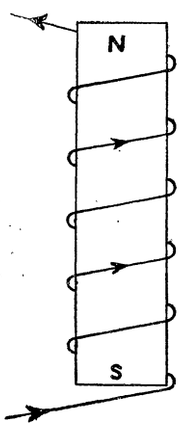

Fig. 1.—Elementary Coil.

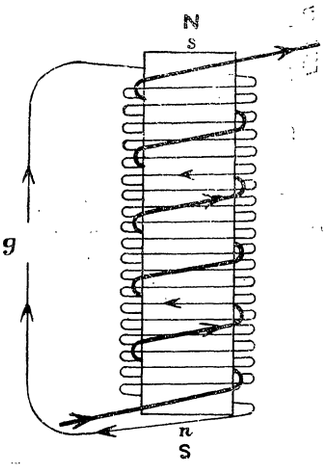

Fig. 2.—Induction Coil at "Make."

50 volts, is started through the circuit. The carbons are then drawn slightly assunder. At the first instant a self-induction spark of the third order of our classification, to be dwelt on later, flies from the positive carbon to the negative. This is accompanied by great heat due to the current, which volatilises into gas some particles of the positive carbon. If now the carbons be drawn not too far apart, this gas will form a conductor for the current from one electrode to the other. The precursory self-induction spark being spent, and the current now flowing continuously through this gas, intense heat is developed owing to the high resistance of the latter. This causes the points of the carbons to become white hot, whence arises the light. They are thereby also slowly consumed; and it is to be noted that the *positive* carbon, or that *from* which the current flows, burns down at twice the rate of the negative. The current flowing continuously through the gas from one carbon to the other, in appearance like a blue ambient flame, thus forms what is known as the voltaic arc.

A marked difference will thus here be noted between the arc and the disruptive spark already enlarged on. For contrary to the case of the spark, the *electrodes* are here distinctly subject to destruction. A body between the electrodes—that is, within the arc, will also be destroyed however, though not by any form of disruption as with the spark. But the intense heat of the arc will burn, melt, or volatilise, almost if not quite every known substance. We shall however return to this point.

Now, as explained, the arc is immediately preceded by, and has for one of its own pre-existent causes, a spark of the third order. To this latter, and the second order, we may now give our attention. Induction and self-induction sparks, like those of the first order, are disruptive. But they differ from the first, not only in being effects of current electricity as intimated, but further in that they have their origin in *magnetism*. This we may now proceed to make more clear.

It is well known that if a coil of wire be made as shown in Fig. 1 herewith, and a current of electricity be sent through it, a magnetic field will be formed within the coils. If the direction of the current be as indicated by the arrowheads, then according to Ampère's well-known law, the polarity of the field thus formed will be as also shown by the letters **N** and **S** If the current be reversed, the poles will also be reversed. On an iron bar moreover being enclosed within the coil as depicted, the magnetic effects will be still greater, owing to the iron having a much greater magnetic permeability than air.

In Fig. 2 are shown two coils, one within the other, having a common centre line, and also enclosing an iron core. Now, especially when an iron bar is enclosed as represented, a further effect may here be realised. This is, that if a *sudden* current be sent through one of these coils, say the interior one, it will *induce* a sudden current running in the *opposite* direction in the other coil. Further, on suddenly breaking the primary current in the interior, a sudden current will again be induced in the outer or secondary coil, but this time in the *same* direction as the primary current, as shown in Fig. 3.

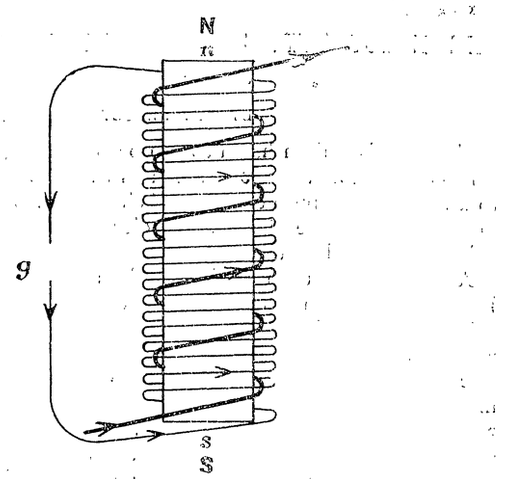

Fig. 3.—Induction Coil at "Break."

In Fig. 2 the induced secondary current tends to produce a polarity opposed to the polarity of the primary coil, as shown by the small and large letters; while in the case of Fig. 3, the secondary polarity augments the primary. But the point immediately to be arrived at is that this *secondary* current is purely a *magnetic* effect, that is, a result obtained through the intervention of magnetic induction. On this we may yet further enlarge.

(To be continued.)

A HIGH FREQUENCY DYNAMO.

No sooner did Messrs. Siemens Bros. propose to show 50,000 volt experiments at the Crystal Palace Exhibition last year than Messrs. Swinburne and Co. offered a 100,000 volt set. The two shows did not materially differ, the arcs and disruptive discharges were very much of the same character in the two cases. Similar competition has been going on in the construction of little dynamos of high frequency. Tesla brought over his 13,000 $\sim$ dynamo; three weeks ago we described Ewing's 14,000 $\sim$ dynamo, giving 5 amperes at 100 volts, and Messrs. Pyke and Harris, in conjunction with Sir David Salomons, have constructed a 16,600 $\sim$ machine giving one ampere at 100 volts. This is about 28 per cent. higher frequency than that of Tesla. The principle of this machine closely resembles that of Prof. Ewing, but the poles are cut on the opposed plane

Hosted by Google

faces of two fly-wheels instead of radially. The diameter of these wheels is one foot, and the poles run about ten to the inch. The zigzag winding on the magnets is of some depth, as in Prof. Ewing's machine, but the armature winding is only of one layer. In order to get a high speed, the plan proposed by Edmunds and Sellon in 1879, Kelway in 1882, and others, to revolve the armature and the fields in different directions has been adopted. This method, while quite impracticable in ordinary dynamo work, becomes possible in this machine, since it contains a direct current motor.

A radial electro-magnet fixed to one half revolves in front of a Gramme ring wound in ten sections. The two parts are mounted on overhung bearings, and the friction of each being approximately the same, they run at about 1,500 revolutions per minute, in opposite directions, giving a relative speed of 3,000 revolutions. The machine is, in fact, a dynamotor, and where a definite frequency is not demanded, such an arrangement may be found convenient. The experimental results can hardly be expected to differ much from those of Tesla, nor does it seem worth while to double or even to quadruple these high frequencies by the device suggested by Mr. Trouton. We understand that it is intended to modify this machine, and we therefore wait further development before presenting details to our readers. An advantage presented by this arrangement is that it is easy to run it for experimental purposes from any 100-volt circuit.

THE ELECTROLYTIC PREPARATION OF METALLIC CHROMIUM.*

BY EM. PLACET.

Metallic chromium has hitherto been nothing but a laboratory curiosity, and in most instances the name has been given to a more or less pure carburet of chromium. I have succeeded in obtaining the metal by a new electrolytic process, which I will succinctly describe.

An aqueous solution of chrome-alum is prepared, to which is added an alkaline sulphate and a little sulphuric or other acid. This solution is then electrolysed. At the negative pole a beautifully brilliant deposit is formed on the surface of the electrode, and this deposit consists of pure chromium. The metal is very hard, and is of a beautiful bluey-white colour. It resists atmospheric action perfectly, and is only attacked by concentrated sulphuric acid, nitric acid, and a concentrated solution of potash. When the electrolytic deposit takes place under certain conditions, it is even possible to obtain arrangements of chromium crystals, which recall the branches of fir trees. This metal, which can now be prepared on a thoroughly commercial scale, furnishes numerous alloys, which are being investigated.

I may add that this new process has led me to investigate "chromage," if such a word be permissible, or the electrolytic deposit of chromium upon the surfaces of different metals and alloys. My experiments have succeeded perfectly. With baths similar to the one described above I have obtained an adherent deposit of chromium of a thickness variable at will and resembling oxidised silver, upon brass, bronze, copper and iron.

I am glad to be able to place before the Académie a specimen of metallic chromium weighing more than a kilogramme; also samples of chromium alloys and brass ornaments electroplated with chromium.

Electric Traction in Belgium.—The Belgian State Railway authorities have, says *Industries*, decided to carry out some experiments with electric traction. The experiments will be carried out in the neighbourhood of Liège, at a point where all conditions of railway operation, such as inclines, curves, &c., are available. In the first trial two waggons loaded with pig iron will be employed, the necessary electric current being supplied by accumulators. Experiments will afterwards be carried on the Petite-Espinette local railway, electric conductors being employed in this case.

EXPERIMENTAL RESEARCHES ON ALTERNATE-CURRENT TRANSFORMERS.†

BY J. A. FLEMING, M.A., D.SC., F.R.S.

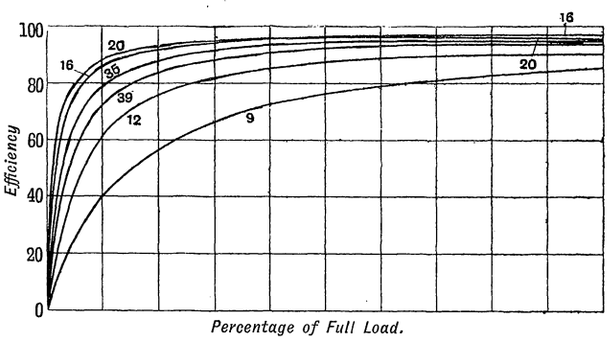
(*Concluded from page 125.*)

Thomson-Houston 4,500-*Watt Transformer.* (Tables XXIII. and XXIV. Figs. 34*, 35, 36*, and 37*.)

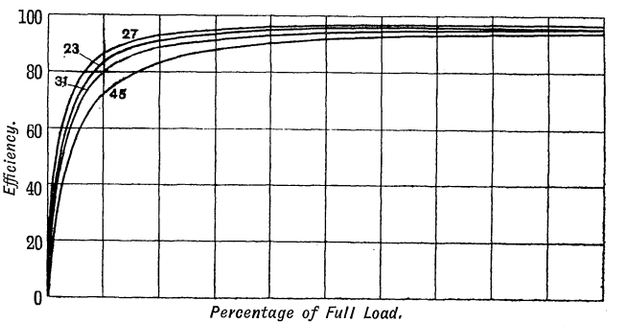
There is nothing which here specially calls for remark. The transformer is a very good example of a high efficiency closed iron circuit transformer of small size. At one-tenth of full load the efficiency is 79·1 per cent. The open-circuit loss is only 1·6 per cent. of the total full secondary output.

Kapp 4,000-*Watt Transformer.* (Tables XXV. and XXVI. Figs. 38*, 39, 40*, and 41*.)

This is a very interesting transformer, having an exceedingly good regulation for such a small size. Its total secondary drop is under 2 per cent. of its secondary voltage at no load, and its open-circuit loss is 2·8 per cent. of full output. It is curious in the rather slow rise of its power-factor as the secondary load is increased. More about this will be said presently. The good regulation of the transformer and small "leakage drop" are no doubt due to the effective "sandwiching" of the primary and secondary coils.



The following are the Transformers of which Efficiency Curves are given. The number against each curve refers to the Figure mentioned in the paper. **9.** 5-H.P. Ferranti (1885 pattern). **12.** Ferranti rewound. **16.** 65,000-Watt Westinghouse. **20.** 15-H.P. Ferranti (1892 pattern). **35.** 4,500-Watt Thomson-Houston. **39.** 4,000-Watt Kapp.



23. 15-H.P. Ferranti rewound (1892 pattern). **27.** 20-H.P. Ferranti (1892 pattern). **31.** 6,000-Watt Mordey. **45.** 3,000-Watt Swinburne ("Hedgehog.")

Swinburne 3,000-*Watt* "*Hedgehog*" *Transformer.* (Tables XXVII., XXVIII., and XXIX. Figs. 42, 43, 44, and 45.)

Lastly, but by no means least, there are several remarks to make about the "Hedgehog" transformer of Mr. Swinburne. As a problem in transformer testing this open-circuit transformer of his is a hard nut to crack. From first to last we have made many hundreds of observations on it. The Tables XXVII., XXVIII., and XXIX. give the results of the two best sets of observations with the dynamometer wattmeter on this transformer. The mean of a number of observations with the dynamometer wattmeter on the power taken up at no load by this transformer gave a value very close to 114 watts. We have already seen that the mean of the three-voltmeter and three-ammeter methods indicated probable values of the power loss close to this number. The dynamometer observations gave values of 114, 108, 108, 114, 114, 121, 121, in seven series of observations at slightly different frequencies. Hence

† Abstract of a Paper read before the Institution of Electrical Engineers on November 24, 1892.

* This figure is omitted because the curves of the transformer closely resemble those which we have given as specimen curves. The actual limits of the other curves may be easily found by referring to our abstract of the tables.

Hosted by Google

the mean of all means of over 62 observations by three different methods gives the value of 112 watts for the power absorbed at no load in this 3,000-watt "Hedgehog" transformer.

The core of this transformer is composed of soft iron wires 18in. in length, and each 0·9225 of an inch in diameter. The total volume of iron wire is about 856 cubic centimetres, and weighs 5,982 grammes. The induction in the centre of the core is about 10,000 C.G.S. units. It is clear that with such subdivision of the iron true eddy-current loss in the iron must be small, and my estimate of it is that it does not amount to more than 10 or 15 watts at the frequency used. Also, the true hysteresis loss cannot probably be much greater than 20 to 30 watts. In general one watt per 30 cubic centimetres of core is about the value of the true total core loss in most usual small-sized transformers. How comes it to pass, then, that all the measurements above described point to a loss of about 112 watts at no load? The answer to this question is, I take it, that there may be considerable eddy-current loss in the copper of the secondary circuit. In this transformer the secondary circuit is first wound on the core, and then the primary circuit over it. If we consider for a moment, we shall see that the lines of induction passing up the core return back through the space outside the core, and in so doing they must cut through the copper of the circuits. Hence, at each reversal of induction, unless the copper circuits are exceedingly well stranded, there are eddy-currents set up in the copper mass; and this takes place equally well at full and at no secondary load. The only way to prevent this waste is to make the secondary circuit of stranded wire, each strand slightly insulated and very small. It is perfectly clear that this loss must take place to some extent, and that it is a special defect of the open magnetic circuit transformer. We may, from one point of view, regard the function of the iron core of a transformer to be the preservation of the lines of induction in the proper place, and making them thread through the aperture of the secondary circuit without intersecting or cutting through the mass of the copper in that circuit.

I proposed to Mr. Swinburne to obtain convincing proof of the correctness or incorrectness of this view by winding an exactly similar transformer with a dummy secondary circuit of string or rope. If such a transformer with only primary circuit were tested, I believe it would show a far smaller power-absorption than the actual transformer does. His firm have not yet been able to try this experiment, but it would be most interesting and satisfactory to have it tried. In any case, it seems to me clear that in the "Hedgehog" tested by us there is probably a large eddy-current loss in the copper, and that this accounts for the abnormally large loss on open circuit, which cannot well be accounted for in the iron core alone, unless phenomenally bad iron has been employed. I venture to suggest, therefore, that Mr. Swinburne should direct his attention to getting rid of this copper eddy loss, because, as it stands, this 3,000-watt "Hedgehog" must be kept down in efficiency from this cause. If we compare the efficiency curve of this transformer with that of a closed magnetic circuit transformer of nearest size, we see that the open magnetic circuit so far gives no advantage in efficiency at the low loads. This "Hedgehog" has an efficiency of about 73 per cent. at one-tenth load, and 94 or 95 per cent. at full load. A transformer with a closed magnetic circuit and of not much greater output can be built to do just as well, or better, than this, as can be seen by an inspection of the efficiency curves of the Kapp or Thomson-Houston transformers. If, however, the eddy-current loss in the copper can be entirely destroyed, and the large magnetising current provided by non-wasteful condensers, the open-circuit transformers may perhaps be made more efficient at low loads than closed-circuit transformers of equal output. To attempt to predetermine the efficiency of this type of transformer as now made by calculations carried out on the assumption that the only internal loss is the eddy and hysteresis loss in the iron, leads to considerable overstatement of the efficiency.

If subsequent experiments should confirm this view that at present there is considerable avoidable loss in the copper circuits of

the "Hedgehog," it is clear we are not yet at the end of our inquiries; and until it has been freed from this defect it does not show inherent superiority over its closed-circuit rival. When it has arrived at the ideal condition, and enjoys the constant presence of a condenser imparting to it its necessary magnetising current, which in the 3,000-watt "Hedgehog" is nearly 50 per cent. of the full-load primary current, we shall be in a position to give it a final verdict, and say if the result could not be just as well obtained by adding the necessary small amount of iron to complete the magnetic circuit.

V.—*General Remarks on the Above Experiments.*

14. On examining all those diagrams in which are delineated the curves of total loss of power in the transformer and the curve of total copper resistance loss ($C^2 R$), we see that in every case the upper curve runs *sensibly parallel* to the lower curve; in some cases most exactly parallel. In the curves for closed magnetic circuit transformers of good design the difference between the total $C^2 R$ loss and the total loss of all kinds is the iron core loss in the transformer. Hence we see that all the experiments lead to the conclusion that *the iron core losses are constant at all loads.* In no case have we found any substantial evidence that the iron core losses are evanescent at full secondary load. This last view has been held by Mr. Mordey and others. Seeing that our methods, when applied to the 6,000-watt Mordey transformer, give practically the same results at no load as Mr. Mordey obtains, it is an interesting matter to inquire how it comes to pass that the calorimetric method employed by him seemed to indicate that the whole loss in the transformer at full load was accounted for by the frictional losses in the copper. At present the writer can offer no explanation of this discrepancy. The above-described observations were all made and plotted out before the appearance of the Paper of Prof. Ayrton and Dr. Sumpner, and shown to many people, but it is very satisfactory to find that their undoubtedly excellent method has conducted them to precisely the same conclusion. Hence we seem to have very good reason to believe that the total internal loss curve of a transformer can be drawn from observations of the $C^2 R$ losses and the total core loss at no load

When we come to consider it, it is very difficult to see on what valid supposition we could conclude that hysteresis loss should be less at full than at no load. The only difference in the magnetic conditions are that in one case the iron is magnetised by a small current acting in one direction, and in the other by the difference between two currents flowing in opposite directions, but governed by the condition that the total ampere-turns remain the same. In a special experiment, I have taken the hysteresis diagram for a soft iron wire employing a magnetising force of 1,000 ampere-turns, in one case produced by 2·5 amperes and 400 turns, and in the other case by 20 amperes and 50 turns. The hysteresis areas for one complete cycle were found to be practically the same—the latter, if anything, the larger of the two. Prof. Ewing's direct evidence on this point will be remembered.

15. These measurements have brought out, in addition, another very interesting fact. In the foregoing tables for each transformer will be seen a column of figures headed "Power-Factor." We have already defined this term as the ratio of the "true watts" to the "apparent watts," or product of the effective amperes and effective volts. This ratio is given for each measurement of the power. We see at once that for closed magnetic circuit transformers of good type, such as the Mordey, Westinghouse, Ferranti, &c., the power-factor at no secondary load begins at a value of about 0·8 or thereabouts. For such types of transformers, however, a very little loading up of the secondary circuit—not more than one-tenth of full load—brings the power-factor up to unity. In Fig. 46 are given three curves showing the progress of increase of the power-factor as the load on the secondary circuit is progressively increased. The upper curve represents the growth of power-factor (P.F.) for the 6,500-watt Westinghouse transformer. Beginning at 0·8, it rises up to unity at about one-tenth of full load. Hence at and after this very little load the apparent watts are the same as the true watts, and the real power taken up in the transformer is quite accurately given by the product of the primary terminal pressure and the primary current, effective, or $\sqrt{\text{mean}^2}$, values being understood. For an open magnetic circuit transformer like the "Hedgehog" the case is quite different. The P.F. begins at a value of 0·08 or 0·06, and it never rises up above 0·8. Hence at no stage of the load is the real power taken up by the transformer anywhere nearly equal to the "apparent watts." A transformer like the 4,000-watt Kapp appears to occupy an intermediate position, and although it has a medium power-factor to start with, its P.F. rises up to unity at about half load. The importance of this fact in alternate-current station working is very great. It shows us, if we have a station wholly supplied with transformers of the type of Mordey, Westinghouse, Thomson-Houston, Ferranti, &c., that the apparent watts supplied to the transformers is the real watts at any hour when all the transformers are more than one-tenth loaded. If, however, the station is engineered with "Hedgehogs," or with that museum of transformers of all sorts and makes which some central station engineers are fond of gathering together—under the idea, perhaps, that they can "hedge" for economy and make up for the vices of one kind by the virtues of another—then in hardly any state of the load will it be safe to assume the identity of the true and apparent measures of outgoing power. We must, of course, here assume that concentric primary cables are not in use, otherwise an error of another kind may be introduced. If we take the case of a station provided wholly with closed magnetic circuit transformers, and consider it as having an average kind of load diagram, say for the whole year—then if the measure of the "apparent units" sent out from the station is taken, I do not think that in general we shall be far out in our estimate of the true units sent out if we deduct from the apparent units about 12 to 15 per cent. and call the remainder the measure of the true units of energy sent out in the whole time.

16. On looking at the curves in which are delineated the values of the primary and secondary currents for each transformer, we note that in these the value of the primary current and 1-24th part of the secondary current is plotted in terms of the secondary output. These curves are very nearly straight lines. In the case of the closed magnetic circuit transformers of large power-factor the difference between these current-values is constant.

Since the winding of these transformers are in the ratio of 24 to 1, it is obvious that the ordinates of the current-curves may be taken to represent the primary and secondary ampere-turns. If we look at the tables and examine the difference between the values of the primary current and 1-24th part of the secondary current, we shall find this difference is sensibly equal to the primary current at "no load," or to the "magnetising current," so called. This is only another way of stating the fact that the resultant ampere-turns are constants at all loads and equal to the ampere-turns at no load. The above is true only for the high power-factor transformers. For the open magnetic circuit transformer it is not the case. In this last the difference between the primary and secondary ampere-turns diminishes as the load increases. This is probably because there is a continual change of the relative phase of the primary and secondary currents in the open magnetic circuit transformer as the load is increased; whereas in the closed circuit, after the first beginning of load, the primary and secondary currents come nearly into opposition with each other as regards phase, and preserve that difference at all greater loads.

There are also, as mentioned, for each transformer a set of curves showing the total secondary drop in volts between no load and any load. Consider the case at full secondary load. The P.D. between the secondary terminals is then less than that between them when the transformer is unloaded; primary terminal P.D. being kept always constant. The difference between these secondary P.D.'s is the "total secondary drop." Part of this drop is due to the volts lost by resistance in the secondary circuit, part by resistance in the primary, and the outstanding portion is the "leakage drop," or lost volts due to magnetic leakage. In all of the "drop" curves a line is drawn in to indicate the "drop" due to secondary resistance, and in some a dotted line is added also to indicate the drop due to the primary resistance. The relation of these parts to the whole drop in volts may be examined as follows for a closed magnetic circuit transformer:—

Let v_1 be the instantaneous value of the potential difference of the primary terminals, and v_2 the same for the secondary terminals, of the transformer. Let i_1 and i_2 be the instantaneous values of the currents, and let R and S be the primary and secondary circuit resistance, and N_1 and N_2 the primary and secondary turns. Then let b_1 be the induction density in the centre of the primary coil, and b_2 that in the secondary, and b the density of the leakage; or, if A is the constant cross-section of the magnetic circuit, let $A\,b_1$ be the lines threading through the primary coil, $A\,b_2$ those through the secondary coil, and $A\,b$ the leakage of lines. Then,

$$A\,b_1 = A\,b_2 + A\,b \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

By fundamental equations,

$$\left.\begin{aligned} v_1 &= R\,i_1 + A\,N_1 \frac{d\,b_1}{d\,t} \\ \text{and} \quad o &= S\,i_2 + v_2 + A\,N_2 \frac{d\,b_2}{d\,t} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Hence, writing a for N_1/N_2, we have, by elimination of b_1 and b_2 between (1) and (2),

$$\frac{v_1}{a} + v_2 + S\,i_2 - R\frac{i_1}{a} = A\,N_2 \frac{d\,b}{d\,t} \quad . \quad . \quad . \quad . \quad (3)$$

Let $v^1 = V_1 \sin p\,t$: then $v_2 = -V_2 \sin p\,t$, because the primary and secondary potentials are in opposite phases. Also, we can write $i_1 = I_1 \sin p\,t$, and $i_2 = -I_2 \sin p\,t$, at all stages of the secondary load very nearly, because the primary and secondary currents are in opposite phases, and the primary current is in synchronism with the primary P.D. at all stages of the load above one-tenth. Also, we can write $b = -B \sin p\,t$, because the "leakage" is deter-

Hosted by Google

mined by, and is in close synchronism with, the secondary current. Hence we arrive, by substitution in (3), at the equation.

$$\left(\frac{V_1}{a} - V_2 - S\left(I_2 - \frac{R}{a} I_1\right)\right) \sin p t = -A N_2 p B \cos p t . \quad (4)$$

The quantity $A N_2 p B \cos p t$ is the instantaneous value of the volts lost by leakage. Hence, taking the $\sqrt{\text{mean}^2}$ value of both sides,* and putting dashes over the letters to indicate that they now stand for the values of the currents and potentials as read on alternate-current ammeters and voltmeters, we get,

$$\left(\frac{1}{a} V_1' - V_2'\right) - \left(S I_2' + \frac{1}{a} R I_1'\right) = A N_2 p B.$$

Since $1/a\ V_1'$ is the value of the secondary P.D. at no load, and V_2' is that at, say, full load, the first term in the bracket is the "total drop." The second term in the bracket is the sum of the copper drop due to the secondary circuit and that due to the primary circuit, and the term on the right-hand side of the equation is the drop due to leakage. Hence, if we have a closed magnetic circuit transformer with windings, say, in the ratio of 24 to 1, we have the following rule for obtaining the true magnetic leakage drop, or volts lost by leakage at full load:—Add together the product of secondary resistance and secondary current and 1-24th part of the same product for the primary circuit. Subtract this sum from the total observed drop, and the remainder is the secondary volts lost by magnetic leakage.

Examining in this way all our transformers, we see that in same, such as the Westinghouse, half the observed drop is due to magnetic leakage; whilst in some, such as the Kapp transformer, magnetic leakage is very small. This is no doubt due to the way in which the primary and secondary coils are interplaced in the Kapp transformer.

From what has been said above, it is clear that we can, from certain figures of observation on a transformer, predetermine all these curves when that transformer is of the closed magnetic circuit type. For if we are given—

(*a*) The primary P.D. of terminals;

(*b*) The primary current at no load, commonly called the "magnetising current;"

(*c*) The primary and secondary resistances;

(*d*) The P.D. of secondary terminals, and the secondary current corresponding to various secondary loads up to full load;—

we can determine the efficiency curve and everything else.

For the product of (*a*) and (*b*) gives us the apparent watts at no load, and if we take 0·8 of this we get the core loss at all loads. Then from the ratio of the primary to secondary volts at no load, and the observed secondary currents and magnetising current, we can calculate the primary currents, and from the currents and resistances get the total $C^2 R$ loss at certain secondary loads. Hence we can draw a total $C^2 R$ loss curve and a total loss curve parallel to it, and from this last determine the efficiency at every stage of the load.

VI.—*Experiments with Mr. Swinburne's Wattmeters.*

17. As mentioned, Mr. Swinburne sent with his transformer a brass-cased wattmeter stated to be adapted for measuring alternating-current power. In most of the tables giving the power absorbed by various transformers will be found a column headed "Total Power taken up in Transformer by Swinburne Wattmeter," and in the "total loss" curves these numbers are plotted as a dotted line, marked "Losses by Swinburne Wattmeter." In various cases we made measurements with the Swinburne wattmeter, as far as it would read, and our own dynamometer wattmeter, either simultaneously or immediately after one another. The Swinburne wattmeter was carefully calibrated on the same non-inductive resistance as the dynamometer wattmeter, and its constant determined. An examination of the values of the power taken up by various transformers at various loads shows that the power values given by the first sent Swinburne wattmeter are in nearly all cases lower, and often much lower, than those given by the dynamometer wattmeter. In the case of the Westinghouse transformer the two instruments gave practically the same value for the loss at no load; and for that transformer, and for the 15-H.P. Ferranti transformer, the differences in the two readings are not great at any load. It seemed that the Swinburne wattmeter gave readings, within reasonable limits of experimental errors, quite as likely to be right as not. The case is quite different, however, when it is applied to measure the power-absorption in a transfer of small or moderate power-factor. In the case of the Thomson-Houston transformer the Swinburne wattmeter gave power values only about two-thirds as great as those given by the dynamometer; in the case of the Kapp transformer rather less. Most remarkable of all, in the case of Mr. Swinburne's own transformer, his wattmeter gave power values on the average only about half of those obtained by the dynamometer wattmeter. Again and again we repeated these experiments, calibrating the wattmeters in various ways, and using every precaution. The mean of all our observations with the Swinburne wattmeter gave 74 watts as the power taken up in the 3,000-watt "Hedgehog" at no load, and the most frequent value obtained was 55 watts. We have seen that the mean of all other methods gave 114, and the most trustworthy observations by the dynamometer gave 121 watts. Here, then, was a riddle to be explained. It was only susceptible of two solutions. Either the dynamometer, three-voltmeter, and three-ammeter results for the "Hedgehog" were greatly in excess of the true value of the power absorbed, or else Mr. Swinburne had achieved the marvellous feat of inventing a wattmeter which, whilst reading approximately correctly the power taken up in transformers of good closed magnetic circuit type, measured too little by nearly 50 per cent. when applied in the same way to test his own.

18. It was felt to be necessary to examine this matter with the greatest care. Experiments were therefore made with three small "Hedgehogs" which had been made for lecture purposes. These transformed from 100 to 33 volts. These three little transformers were arranged with their primary circuits (100 volts) in parallel, and with their secondary circuits open. The power taken up in the three together at 100 volts was measured by the three-voltmeter method, the dynamometer wattmeter, and with the Swinburne wattmeter. These experiments were carried out as follows:—In series with the transformers was placed a couple of incandescence lamps as a non-inductive resistance, and three Kelvin multicellular electrostatic voltmeters were employed in a three-voltmeter method to measure the power absorbed in the transformers. The resistance of the lamps was obtained by a measurement of the current passing through the lamps, using either a Kelvin ampere balance or a dynamometer placed behind the voltmeters. With these arrangements, and using a very steady pressure, and such ratios of the potential differences as would give the best results, we obtained 11 measurements of the power absorbed at no load by these three little "Hedgehogs." These results are tabulated in Table XXXI. Then, next, both the Swinburne wattmeter and the dynamometer wattmeter were carefully standardised on an incandescence lamp working at 100 volts; measuring first the true power taken up in the lamp by volts and current, and then using this value to obtain the constant of the wattmeters. The standardised wattmeters were then set to measure the power taken up in the three small transformers. The results are given in Table XXXII.

Collected Results for the Mean Value of Power absorbed by the Three Small "Hedgehogs" arranged in Parallel.

By three-voltmeter method	19·26 watts.
By dynamometer wattmeter	19·16 „
By Swinburne wattmeter	12·61 „

We see that the mean value of the power taken up as measured by the three-voltmeter method agrees quite well with the value obtained by the dynamometer wattmeter, but that the value obtained by the Swinburne wattmeter is nearly 34 per cent. lower than the other two. These experiments, which were very carefully made, convinced me that the cause of the discrepancy must be looked for in the Swinburne wattmeter.

Mr. Swinburne sent for use with his transformer a condenser suitable for putting upon the primary circuit in parallel with the primary circuit of the "Hedgehog." We therefore applied the two wattmeters to measure the power taken up (1) in the condenser alone, (2) in the transformer alone, and (3) in the condenser and transformer on open secondary circuit when the condenser was joined in parallel with the primary of the transformer. The primary pressure was 2,400 volts in all cases. When the condenser was across the circuit alone, the current flowing into it was 0·458 ampere, as measured by a Kelvin balance. Since the frequency was 83, this shows the capacity of the condenser was about 0·36 of a microfarad. The magnetising current, or open-circuit current, of the 3,000-watt "Hedgehog" was 0·761 ampere; and when "Hedgehog" and condenser were joined in parallel the current flowing into them jointly was 0·283 ampere. The Swinburne wattmeter and dynamometer wattmeter being both standardised, 12 measurements were taken with each instrument—four of the power absorbed in the condenser, four of that absorbed in the transformer with open secondary, and four of the condenser and transformer joined in parallel. The results are given in Table XXXIII.

It is clear, therefore, that whilst relatively to the dynamometer wattmeter Mr. Swinburne's first wattmeter reads too low on his transformer, it reads too much on his condenser, and he has been overrating the power taken up in the condenser to about the same extent as he has been underrating that taken up in the transformer.

On thinking over these results, it became evident that they could be accounted for on the supposition that the current through the shunt circuit of the Swinburne wattmeter was *advanced* in phase as compared with that of the primary impressed potential difference between the ends of that circuit. The correctness of the wattmeter as a power-measuring instrument depends upon the current in the shunt circuit being exactly in step, or consonance, with the periodic potential difference at the ends of that circuit. When the wattmeter is applid to the open-circuit transformer, the current through the transformer, which is also the current in the series coil of the wattmeter, lags behind the P.D. at the primary terminals of the transformer. Hence, if the current through the wattmeter shunt circuit (which should represent that P.D. in phase and magnitude) is advanced in phase, the two currents (series and shunt) in the wattmeter will have a greater difference of phase impressed upon them, and hence the mean product will be diminished. Again, if the wattmeter is applied to a condenser, the current through the condenser is normally in advance in phase of the P.D. at its terminals. Hence, by the same reasoning, any cause tending to advance the phase of the current through the shunt circuit of the wattmeter will bring the shunt and series currents more into step and increase the mean product. Therefore the wattmeter reading will be too little on a transformer and too great on a condenser.

It is obvious that this advancement of phase of the current in the shunt circuit of the wattmeter could be produced by *capacity* in that circuit. The resistance of the shunt circuit of the Swinburne wattmeter is about 100,300 ohms; of that, the moveable coil has 300 ohms resistance, and the 100,000 ohms is the resistance of the doubly wound fine wire in two brass boxes, which are joined in series with the bobbin. Experiments were then made to see if we could, by artificially increasing the capacity of either of these parts of the shunt circuit, exaggerate the defect, and, if so, whether the readings of the wattmeter on the "Hedgehog" were more altered than readings on a non-inductive resistance.

Experiment 1.—A small Leyden jar of 1 pint size, about 0·001 or 0·0005 of a microfarad in capacity, had its inside and outside coatings connected to the ends of the external resistance (in brass boxes) of the shunt circuit. So arranged, the Swinburne wattmeter was applied to measure the power taken up in the 3,000-watt "Hedgehog" on open circuit and in our non-inductive resistance. With the jar removed, the deflection of the wattmeter was five divisions, corresponding to about 80 watts taken up in the transformer. With the jar added, the deflection fell to 0·3, or 5 watts. No such change was produced by adding the jar when the power being measured was being taken up in the non-inductive resistance. It is evident, therefore, that capacity added to the shunt circuit still further reduces the wattmeter readings.

Experiment 2.—In order to find out, if possible, whether the prejudicial capacity existed in the external resistance in the brass boxes or in the internal resistance in the moveable bobbin of the shunt circuit, the brass boxes were removed and their place taken by a resistance of 34,000 ohms, made up of the filaments of high-resistance incandescence lamps. It seemed clear that a row of lamps could have no sensible capacity. The readings of the wattmeter were then compared when the shunt circuit external resistance consisted of 34,000 ohms made up of lamp filaments, and 100,000 ohms made up of doubly coiled wire in brass boxes, being taken both on the 3,000-watt "Hedgehog" and on a 15-H.P. Ferranti transformer. No greater difference was found in the power measurements in the two cases than might be due to errors of reading. For the "Hedgehog" the power reading with the external resistance of lamps was 79 watts, and 81 watts in the case of the wire resistance. For the other transformer values of 125 and 130 watts were found. Hence it appeared to be more probable that the capacity giving rise to this diminished power reading might be due to the small electrostatic capacity of the tightly coiled wire bobbin of very many turns which forms the suspended circuit of the wattmeter, and that this capacity advances the phase of the current in the shunt circuit, so that instead of being exactly in step with the P.D. on the terminals of the transformer it is slightly in advance of it.

Subsequently to the date of the experiments above recorded, Mr. Swinburne sent a second wattmeter of similar character, but differing from the first sent in that it had an ebonite outer case and no metal frame near the moveable coil. This second wattmeter was carefully compared with the first one and with our own dynamometer wattmeter. The three wattmeters were standardised, and their constants determined by noting the instrumental readings when the instruments were set to read the known power taken up in the standard inductionless platinoid resistance arranged to absorb 600 watts at a P.D. of 2,400 between its terminals. The so-calibrated wattmeters were then set to read the power taken up in the 3,000-watt "Hedgehog" on open circuit, the Swinburne condenser, the old Ferranti 1,850-watt transformer, the Kapp and Thomson-Houston transformers. The results are given in the table below.

Table XXXIV.—*Comparison of Wattmeter Readings on various Circuits.*

Reading of dynamometer wattmeter, in watts.	Readings of Swinburne wattmeters in watts.			Object tested.
	Second pattern.	First pattern.		
		Case on.	Case off.

156	154	112	—	Kapp transformer
303	282	—	—	Ferranti transformer

Hosted by Google

It is clear from the above observations that the second wattmeter with ebonite case agrees much more nearly with the dynamometer wattmeter than does the first having a brass case. The differences between the second wattmeter and the dynamometer are quite within the limits of errors of observation, seeing that the instrumental reading for 15 watts is only about 0·5 of a scale division on all instruments. It is evident, therefore, that the second wattmeter sent by Mr. Swinburne is a very different instrument from the first one. The writer is unable to say whether it differs in any way from the first one, except in having an ebonite instead of metal case, and in having no metal supports near the shunt coil, but it is obvious that the displacement of phase of the shunt current no longer takes place. According to the view above stated, this displacement is the consequence of a capacity effect. It is difficulty to see how eddy-currents set up in any metal near the moveable coil could create the observed defects in accuracy; because, although these might weaken the resultant field in which the moveable bobbin hangs and so make the wattmeter readings too low, we have to account also for the fact that the first wattmeter reads too much on a condenser. It is evident, however, that the second wattmeter Mr. Swinburne sent me is a fairly accurate instrument, whereas the first one is quite unreliable on circuits of small power-factor.

Before we christen a wattmeter a "non-inductive wattmeter," it should be carefully tested on inductive circuits of small power-factor and large capacity or inductance.

VII.—*General Remarks on the use of Dynamometer Wattmeters to Measure Alternating-Current Power.*

The foregoing experiments impressed upon us the necessity for caution in concluding that any wattmeter of the dynamometer pattern, and however made, would give correct readings of the alternating-current power taken up in an inductive circuit. If we consider a simple harmonic current, I, in, and potential difference, V, at the ends of such an inductive circuit, then the mean value of power, W, taken up in the circuit is $\frac{1}{2}$ I V cos ϕ, where I and V are the maximum values during the period, and ϕ is the phase difference of I and V. If ϕ varies, then the rate at which the measurements of the power W is varied is expressed by $d\,W/d\,\phi = -\frac{1}{2}$ I V sin ϕ, and the ratio of d W/W is therefore equal to - tan $\phi\, d\,\phi$. Hence a small change in ϕ produces a greater effect on the value of the error in measuring the resulting power in proportion as ϕ increases from 0° to 90°.

In the case of an open-circuit transformer there is a very considerable difference of phase between the primary current at no secondary load and the difference of potential between the primary terminals.

Accordingly, if a wattmeter of the dynamometer type is applied to measure the power being taken up in such a transformer at no load, there is a correspondingly great difference between the phases of the currents in the shunt and series coils of the wattmeter. If, then, either by reason of capacity or inductance in the shunt circuit, the phase of the shunt current is displaced by a small amount, the percentage change so introduced into the mean product of the currents—*i.e.*, into the wattmeter reading—is much larger than if the instrument was being used on a transformer of large power-factor.

Hence, in the employment of such a wattmeter it is desirable that the moveable part of the shunt circuit should have very few turns, and that all metal framework near it be avoided. Generally speaking, it will then be difficult to bestow upon the shunt coil sufficient magnetic moment unless the current in it is comparatively large. This means that considerable power will be dissipated in the wattmeter itself. It is better, however, to employ a wattmeter which uses up a few horse-power and obtain accurate results with it, than reduce its shunt circuit to a small value and introduce sources of error. It is as necessary to avoid capacity as to annul self-induction in the shunt circuit. As to the external non-inductive resistance in series with the shunt coil, we have, as seen, always preferred to employ a series of incandescence lamps. There is no difficulty in doing this when the means exist for keeping the P.D. between the primary mains constant. Large circuits of incandescence lamps in series are, however, rather unwieldy and expensive. I have been experimenting lately with other methods to obtain the necessary non-inductive resistance for the external shunt circuit of the wattmeter cheaply and in a compact form. The conclusion arrived at, however, is that, with proper precautions, a suitable dynamometer wattmeter is a very useful instrument to employ for measuring in a practical workshop-like way, the power being taken up in inductive circuits, and that it is much more easy to manage than any of the many other complex methods which look so well on paper and are so difficult to carry out satisfactorily in real life. In any case, a practically non-inductive metal wire resistance is necessary wherewith to standardise the wattmeter *in situ* and before use; and if the moveable coil has very few turns, and no metal near it, and the external shunt circuit is of proper kind, excellent results in measuring alternating-current power may be obtained with it

VIII.—*Experiments on the Magnetic Behaviour of Transformers at the Moment of Connecting them to a Circuit.*

More than fourteen months ago I carried out a series of experiments and observations on the behaviour of transformers at the moment of switching them on to a "live" circuit, and which are, I venture to think, of some practical importance. They arose out of facts which came to my notice regarding instances of sudden failure of transformers at the instant of closing the primary switch. Transformers have been known to be pierced or to break down on switching on after having worked well for a long time. To investigate the behaviour of transformers at the moment of closing the primary switch and connecting them to a high-pressure "live" circuit, the following experiments were tried:—

Experiment 1.—The secondary circuit of a 4-inch spark induction coil (kindly lent by Mr. Apps) was closed by a vacuum tube of a very sensitive kind. It had long overlapping platinum electrodes. The ordinary primary coil with iron core was removed, and its place filled by a bobbin of 12,000 turns of insulated copper wire wound on a wooden core. This primary coil could be slid into or out of the secondary coil. The primary coil was placed in series with the primary circuit of a 40 H.P. transformer, the "magnetising current" of which was 0·137 ampere. When the transformer had its secondary circuit open, this magnetising current in the primary flowing through the primary coil of the induction bobbin just sufficed to keep up a glow, visible in the dark, in the vacuum tube. The primary coil of the induction bobbin was then withdrawn from the secondary until the glow in the tube just disappeared. Under these circumstances the vacuum tube was an exceedingly delicate detector of any sudden increase in the primary current. If the primary circuit of the transformer was then suddenly and frequently opened and closed by a switch, it was found that at intervals, on some occasions of closing the primary switch, the vacuum tube flashed up brilliantly, thus showing that a rush of current far exceeding the normal magnetising current took place into the transformer on some occasions when the primary switch was closed.

Experiment 2.—Another way of detecting this rush of current is to insert in the primary circuit of the transformer an incandescent lamp, which is brought to proper incandescence by the normal magnetising current of the transformer. Thus, in one of our experiments, a 10-candle incandescent lamp, taking 0·33 ampere, was placed in the primary circuit of a 5-H.P. transformer, the magnetising current of which was 0·35 ampere. When the secondary circuit of the transformer was left open and the primary switch suddenly closed, on most occasions the lamp came quietly to normal incandescence; but on some occasions, on closing the primary switch, the lamp flashed up brilliantly, so much so as to blacken the glass, and in some cases even to break the filament. This experiment showed in a striking manner the sudden rush of current into the transformer on closing the primary switch.

Experiment 3.—In another experiment, a Kelvin centiampere balance was inserted in the primary circuit of a 40-H.P. transformer, of which the normal magnetising current was 0·17 ampere. The balance was adjusted so as to be in equilibrium when this current was passing, and the primary current was then switched on frequently. On some occasions the balance was thrown up violently, even when the weight was moved into positions corresponding to 5 or 10 amperes. In one case, the weight being at the position corresponding to 10 amperes on the balance, the balance was thrown up violently at the third switch-on. On other occasions, the weight being at the position corresponding to 10 amperes, the balance was thrown up at the 5th, 11th, and 13th time of switching on, whilst on the other occasions it was not moved. In one instance the beam of the balance was thrown up so violently that the weight, having a mass of about 66 grammes, was completely thrown off the scale pan; thus indicating that on that occasion an immense rush of current passed in the transformer at the moment of closing the primary switch, but which current sank again almost instantly to the steady value of 0·137 of an ampere.

Experiment 4.—The safest and by far the most convenient method of showing this rush of current was found to be the employment of a simple form of dynamometer placed in the primary circuit. Two flat coils were constructed of No. 20 covered copper wire, each coil having 23 turns coiled up as a sailor coils a rope, the external diameter of the coil being 5½ inches. These flat coils were suspended by silk ribbons on a vertical plane, facing one another. The coils had straws cemented to them, which hung down like the leaves of a gold-leaf electroscope. By means of flexible connections, the primary current of the transformer could be passing through both coils in series in such a direction that the coils tended to repel one another when the current was passing. The weight of the coils was such that when the normal magnetising current of the transformer was passing the repulsion was hardly visible. On switching on and off the primary current a great many times, on certain occasions the coils were flowing widely apart, so that the straws, which were about 8 inches long, diverged from one another like the leaves of a gold-leaf electroscope when an excited glass rod

Hosted by Google

is brought near them ; the divergence being such as to cause the tips of the straws to separate about 6 inches. This arrangement could be conveniently inserted in the primary circuit of any transformer, and adjusted so as to show the sudden rush of current on some occasions when the primary circuit was closed.

Experiment 5.—On those occasions when the sudden rush into the transformer took place, a violent thump, or knock, was heard in the transformer. The suggestion was made by Mr. Partridge to employ a wooden rod pressed against the transformer in order to listen to the internal sounds. Accordingly, a transformer stethoscope was constructed, consisting of a rod of deal with a piece of ebonite on one end and a circular disc of pine on the other. By pressing the ebonite against the iron core of the transformer and putting the ear against the wooden disc, it was found possible to study these internal noises in the transformer. On listening to the character of the sound made on switching on a transformer, it was found that on some occasions there was hardly any noise ; on others, a slight knock, or thump, or loud tick ; and on others, a still more violent noise ; and the violent noise always occurred when the other appliances showed a sudden rush of current taking place into the transformer. It is clear, therefore, from these experiments that something peculiar happens on some occasions on closing the primary switch of a transformer having an open secondary circuit, at the moment when the primary current is connected to the "live" circuit. On considering the matter carefully, it became evident that the conditions under which the transformer is disconnected from the circuit must determine what happens when that transformer is reconnected to the circuit. If the current is flowing into the primary circuit of a transformer, and the switch is opened, as long as the arc continues at the switch, so long does the alternating current produce in the iron core an alternating magnetism ; but, at some instant, the arc breaks suddenly, and the primary current is then interrupted. The transformer, therefore, is left magnetised in some particular phase—either strongly magnetised one way or the other, or, perhaps, not magnetised at all, depending on the phase of the current when the current finally ceases. It is clear that on switching on the current again the switch must be clos d in some particular phase of the pressure, and that, therefore, the incoming current finds the iron of the transformer already in a magnetic condition. It may be that the magnetism of the iron is in such a direction that the current is able to produce instantly the necessary counter electro-motive force to keep down the current to its normal mean value ; but it may be that the magnetism of the core is in such a direction that the first change which takes place in the magnetic condition of the core is one which, so far from introducing a back electromotive force into the primary circuit, actually assists the current. In other words, the self-induction of the tranformer is non-existent for the first moment, and until the current has got the core into proper magnetic condition, in proper relative step with itself, there is not sufficient impedance in the primary coil to prevent the impressed electromotive force making just whatever current it can, so far as the true, or "ohmic," resistance of the primary circuit will allow. Under these conditions, therefore, it is evident that there must be a great rush of current into the transformer, until the impedance is built up by the magnetism of the core falling into proper relative step with the current.

Experiment 6.—It was considered advisable to find out whether this sudden rush of current into the transformer was accompanied by an increased potential difference between the primary terminals of the transformer ; accordingly, the induction coil and vacuum tube employed in experiment 1 were arranged so that the primary circuit of the induction coil was in series with a non-inductive resistance placed across the primary mains, in parallel with the primary circuit of the transformer. It was expected that if a rise of pressure took place on switching on the transformer, the vacuum tube would indicate it by flashing up ; but the experiment failed to indicate any rise of pressure, even when the primary coil of the induction coil was adjusted as carefully as possible to show any increase in pressure between the primary mains.

Experiment 7.—The following method was then tried :—Two brass balls, about 1 cm. in diameter, carried by horizontal screws, having 24 threads to the inch, passed through fixed nuts on an insulating stand. One of these screws had a large divided ebonite head, or arm, to serve both as a handle and an index. This discharger was placed in series with a primary fuse across the primary mains, in parallel with the transformer. The balls were then screwed up until just in physical contact, and afterwards separated by such a distance that the alternating pressure employed between the primary mains—namely, 2,400 volts—just could spark across the distance. This sparking distance was found to be about three-quarters of a millimetre. Having determined this sparking distance, the balls were further separated by such a small amount as just to prevent the normal pressure from sparking across. This arrangement being kept in parallel with the primary circuit of the transformer, the primary current was then switched on and off a good many times, and on some occasions the spark jumped across the spark balls at their increased distance, thus showing an increase of pressure. The greatest distance between the balls across which the spark was found capable of jumping was 0·84 of a millimetre. Other experiments were made to determine what alternating pressure would jump across this increased distance. It was found to be something not exceeding 4,000 volts.

The above experiments were varied in many ways, but they all went to prove that at the instant of switching the transformer with an open secondary circuit on to the primary mains, a sudden rush of current may take place into the transformer, and a sudden rise of pressure at the terminals of the transformer.

Experiment 8.—It was deemed advisable to ascertain whether the rush of current into the transformer was a continuous rush—that is to say, a rush all in one direction, lasting over a certain fraction of a second—or whether it was an alternating rush—that is to say, a great increase of current, but at the same time maintaining the normal alternations. In order to settle this point, the flat coils before described in Experiment 4 were arranged so that the primary current of the transformer flowed through one coil, whilst the other coil was traversed by a continuous current produced by a secondary battery. If the rush of current into the transformer is a current always in the same direction, lasting a sensible fraction of a second, it was thought probable that a repulsion would take place between the two coils, one traversed by the steady current, and the other traversed by a current into the transformer ; but no such repulsion was found under any circumstances.

It seems probable, therefore, that this rush of current is an alternating rush, and that it is simply due to the fact that until the magnetisation of the core has settled down into the proper condition, the impressed alternating electromotive force produces whatever current it can through the primary coil, being only limited in so doing by the true resistance of the primary coil.

Experiment 9.—It was considered important to ascertain how this rush into the transformer could be prevented. It is obvious that it can be entirely destroyed by inserting a sufficient non-inductive resistance into the primary circuit, which is gradually removed in place of suddenly closing the switch.

A better method, however, was suggested by Mr. Reginald Brougham—that is, to wind on the transformer a small tertiary circuit. This tertiary circuit is made to take current from another small transformer, which is kept in permanent connection with the primary main, and by means of which the core of the transformer to be connected is magnetised in the proper manner and in the proper direction for producing instantly the necessary opposing electromotive force in the primary circuit when the primary switch of that transformer is closed. When this is done, there is never any "bang," or sudden current-rush, on closing the primary switch of the transformer under test. As a matter of fact, it has been found that when a bank of transformers is being fed from one primary circuit, and feeding their secondary currents into one secondary circuit, then, provided that one of the transformers of the lot is kept connected both to the primary and secondary sides, it is amply sufficient to proceed in the following manner in connecting in other transformers, in order to obtain perfect immunity from any harmful rush of current :—The transformer to be connected to the circuit is connected first on the secondary side, and although this process does produce a rush of secondary current back into the transformer, yet, nevertheless, the rises of pressure that take place never seem to be very serious. The transformer core being thus magnetised in proper relative step with the primary pressure, the primary circuit can be closed, and under no conditions then will there be any sudden rush of current into the transformer.

Experiment 10.—Many experiments were tried to find out what was the minimum resistance necessary to prevent this rush in the various sizes of transformers. It is obvious that a switch which closes the primary circuit, first by inducing resistance, and then gradually removing it, will sufficiently prevent any obnoxious rush of current into the transformer, because the impressed electromotive force is held back, as it were, by the additional resistance from producing excessive current until the magnetism of the core has had time to fall into proper step.

Experiment 11.—Many effects due to similar causes can be produced in open magnetic circuit transformers. In switching off an open-circuit transformer, such as the "Hedgehog," when the secondary of the transformer is on open circuit, a very strong arcing is sometimes observed at the switch ; and the shorter the magnetic circuit of the transformer, the worse does this effect become. On one occasion I had brought to my notice an experimental transformer of an open-circuit type, the iron core of which was remarkably short in comparison with its width. This transformer had a remarkable property—that, after having been connected to the primary circuit, it could not be disconnected as long as the secondary circuit of the transformer was open, without making an immense arc at the switch.

Hosted by Google

The rough explanation of this fact appears to be as follows :—In the open magnetic circuit transformer, especially if the iron part of the magnetic circuit is very short, the average value of the rate of change of induction or of the back electromotive force decreases much more rapidly as the mean value of the current decreases than is the case in closed magnetic circuit transformers. Hence, when in the case of the first-named transformer the primary switch is opened, the immediate reduction of the primary-current strength removes the greater part of the back electromotive force, or opposing counter electromotive force of induction, and greatly increases, therefore, the resultant electromotive force in that circuit. An arc, therefore, continues to follow the switch points as they open, for a considerable distance. In the case of the closed magnetic circuit transformer this is not the case. The initial reduction of the current-strength as the primary switch opens is not accompanied by so great a reduction in the mean rate of change of the induction, and, therefore, of the back electromotive force. The resultant electromotive force in the circuit does not, therefore, rise much, and the switch points are soon beyond the distance at which an arc can be maintained.

Such an arcing can be subdued in the case of a very short iron magnetic circuit transformer by closing the secondary circuit. The mutual induction of the circuit then assists in creating a greater back electromotive force in the primary circuit, and so keeps the resultant electromotive force small as the switch points open.

There are several effects of this kind observable in the process of connecting or disconnecting large condensers to or from high-pressure alternating circuits. There is, in fact, always a risk of breaking down large condensers at the moment of putting them on or off alternating-current circuits, and this appears to be connected with a peculiar behaviour of an alternating-current arc between metallic surfaces, in virtue of which it acts like a resistance of large self-induction.

Conclusion.

There are very many derivative matters which, if space permitted, might be discussed as consequences of facts observed in the course of the above-described researches. It is evident, for instance, that the last word has by no means been said on the subject of design of transformers. I have every hope that before long transformer manufacturers may be able to produce transformers of 25 H.P. and upwards, having close upon 90 per cent. efficiency at one-tenth of full load. When that is done, it will be interesting to repeat some of those calculations which have already been made as to the relative cost of delivering a certain number of thousand units on an average load diagram, say for distances of 1,000, 2,000, 3,000 yards, &c., by low-pressure feeders and by high-pressure plus transformer feeders. Calculations of this kind can be made with some degree of confidence now that it seems clear that the iron losses in transformers are constant at all loads, and that there is a definite relation between this loss and the open-circuit or magnetising current. We can hardly regard the great controversy of open *versus* closed magnetic circuits as entirely and definitely settled, but there is no reason to believe that the majority of those who have designed transformers with closed magnetic circuits have been supremely unwise in their faith or in their works.

In the matter of transformer testing, the experience gained in obtaining the facts brought before you has established in the writer's mind at least the feeling that a properly constructed dynamometer wattmeter is perhaps the best workshop instrument to use for this purpose, but that its personal character must be strictly examined before trusting too implicitly to the results obtained by it.

In conclusion, it will only be right to make mention of those who have assisted me in the somewhat arduous work of taking the observations here recorded. The principal share of this has been borne by my assistant, Mr. Shields, who has worked with great perseverance and care for many months in taking the actual observations, and this in many cases required some painstaking work. He was assisted at intervals by Messrs. J. and D. Morris, students in University College, London, especially in those observations in which the careful simultaneous reading of several instruments was required. The observations on the sudden rush of current into transformers were made for me by Mr. Wordingham.

The facts and measurements thus obtained have in all cases been sifted and repeated with the greatest possible care, with the desire to arrive at conclusions which should be worthy of confidence, and useful to those engaged in transformer manufacture and design.

The discussion on Dr. Fleming's Paper was opened on December 1st, by Mr. J. Swinburne, who attributed the errors of the wattmeter to eddy currents in the brass case of the instrument. He denied that the losses in the Hedgehog transformer were due to eddy currents in the copper, but admitted that such currents were set up in the core which was violently compressed during winding. An abstract of the discussion will appear in our next issue.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 25, 1892.

The Chicago and St. Louis Electric Railway.—Considerable comment has been excited during the past week by the rumour that the General Electric Company would take a financial interest in this line. Early in the week one of the financial news agencies of the city made the statement that the recent issue of $6,000,000 in 5 per cent. Debenture Bonds by the General Electric Company was for the purpose of raising funds for this enterprise. The General Electric officials have been very reticent about giving information as to the purpose for which the bond issue was made, and, of course, there was more or less guessing regarding it. It seems that Dr. Wellington Adams, in an interview at St. Louis, had said that during his recent trip east he had made a deal that put all worry about finances out of the way; and when this issue of General Electric Bonds was made it was surmised that it was for this purpose. General Electric officials are out to-day with a practical denial of the rumour, saying that they have no intention of backing the project financially, but that in case the equipment of the line should be entrusted to them, they would have no hesitation in undertaking it. It is highly probable that should this concern take hold of the equipment of the projected line which—as your readers will remember—is to be constructed between the two cities in a bee-line over a distance of 250 miles, the work would undoubtedly be pushed forward and completed in time for the World's Fair traffic. The project is certainly becoming a matter of more general interest, and one which railroads, as well as electrical engineers, are now discussing from a business as well as an engineering point of view. The construction of the line has already been inaugurated and will be carried forward rapidly. A section at about the centre of the line, 10 miles in length, is already graded, and the right of way has been secured over a large part of the entire line, including a section 29 miles long at the Chicago end of the road. This section takes in the entrance through the suburban and business part of the city of Chicago, and is probably the part which would be the most difficult to secure.

The Edison Lamp Patent Suit.—The injunction recently obtained by the Edison people in their big lamp patent suit, it will be remembered, was against the United States Electric Lighting Company. This Company, it now appears, has turned over its entire business to the Sawyer-Man Company, and an injunction is now sought by the Company controlling the Edison patent to prevent the Sawyer-Man manufacture of lamps. Under ordinary circumstances it might appear that the decision would merely be a repetition of the former one, but this time a number of different questions will arise. The Sawyer-Man Company is, as is well known, at the present time a branch of the Westinghouse Company, while the Company controlling the Edison patent is the General Electric Company, so that the fight is now between the General Electric and Westinghouse Companies. The Westinghouse Company admits that the lamps now turned out by the Sawyer-Man Company are an infringement on the patent just sustained by the United States Court of Appeals, and expresses its willingness to go out of the lamp business so far as this particular kind of lamp is concerned, but asks for time to do it in. The principal question, however, to be decided, is one raised by the Westinghouse Company to the effect that the General Electric Company being a "most vicious trust," established in violation of the laws of the State of New York, has no standing in court. By agreement of the counsel in the case a preliminary injunction was granted in the lower court, which, however, was stayed until the matter can be brought up before the United States Court of Appeals, which is the same court that recently passed a decision on the Edison lamp patent. The question to be decided, it is evident, is a very important one, and the decision of the Court of Appeals will be awaited with interest. It is expected that the matter will be pushed forward as rapidly as possible, and that the decision will be reached before the end of the year.

CORRESPONDENCE.

FIRE AT THE LONDON STEREOSCOPIC COMPANY'S PREMISES, REGENT-STREET.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been called to a letter you publish in your last issue signed "J. D. F. Andrews." The statement he makes therein, that I examined and passed the electrical installation at the London Stereoscopic Company's premises, contains not a single word of truth. I knew nothing whatever about the installation, nor were any of the insurances effected in the Phœnix Fire Office.

With regard to Scott's Oyster Rooms, I never saw the installation, nor was I even aware that the electric light was on the premises. Neither was the Phœnix Fire Office aware that there was any electrical installation, the work having been placed up some years ago, when the premises were insured in another fire office. As to whether there is the slightest justification in laying the charge of the fire to electricity, I leave those concerned to say, if they think it worth their while. I must request you to publish this letter, as the false and misleading manner in which Mr. J. D. F. Andrews has made use of my name makes me depart from my rule of passing unheeded erroneous or unjust statements in print with regard to myself or my work.—Yours, &c., MUSGRAVE HEAPHY.

London, Dec. 6, 1892.

[We sincerely regret the annoyance which the inadvertent publication of Mr. Andrews' statements has caused Mr. Heaphy and the Phœnix Fire Office. The fire at Scott's Oyster Rooms was recorded in *The Electrician* of May 27, 1892, when we stated that the work had not been inspected by the Phœnix Office. The Phœnix Fire Office has never become liable for any risk undertaken by them under their Electric Lighting Regulations, which were framed so long ago as February, 1882.—ED. *E.*]

VARLEY TESTIMONIAL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We shall be glad if you will allow us the opportunity of calling the attention of your readers who are interested in the above to the fact that, although we have received encouraging responses and subscriptions from some of those we expected to aid us, yet the response has, as a whole, up to the present been disappointing, more especially on the side of the manufacturing community. We are sure that it will be found in most cases that this is due to our circular letter of appeal having been overlooked, owing to its being sent out during the season when a good many members of the electrical profession were away on their holidays.

The object of this letter is to remind them and all others who have benefited by the undoubted impulse which Varley's inventions gave to electrical engineering, to send in, without further delay, their subscriptions according to their means to Mr. A. Stroh, 98, Haverstock-hill, N.W., endorsing subscriptions to Varley Testimonial Fund.—Yours, &c.,

A. STROH, Hon. Treasurer.
R. E. CROMPTON, Hon. Sec.

December 5, 1892.

GILBERTIANA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been drawn to the paragraph in your American Notes on p. 135, in which there is a statement that a translation of Gilbert's "De Magnete" is about to be brought out in the States, and which further refers to the Gilbert Club, of which I have the honour to be one of the secretaries.

I think your American correspondent must be under some mistake in attributing the proposed translation to Mr. Mottelay, who is an honourable gentleman. He visited me at my laboratory rather more than a year ago, when we talked of Gilbert and of the Gilbert Club, and its long-cherished work. He then begged me to enter his name in one of the then few remaining places in the list of the members, that in due time he might receive the copy of the English translation of "De Magnete." He is not the man to lend his name in an underhand way to an attempt to depreciate the careful work that has been going on for three years by the Editing Committee of the Club.

As to this alleged American translation, it is quite enough for most persons to know that its publishers are to be Messrs. J. Wiley and Sons, of New York, who have earned for themselves evil notoriety by their pirated editions of Ruskin's works. The Gilbert Club may well ignore anything emanating from so tainted a source.

As to the last part of your correspondent's paragraph, which relates to the affairs of the Gilbert Club, I will only say that down to the present time the club has not asked for a single subscription from any of its members, nor will it do so until its translation of "De Magnete" is ready for distribution. All the preliminary expenses of its foundation have been met without yet calling on the treasurer. It is true that a very few of the members spontaneously remitted their guinea apiece; and these subscriptions remain intact, awaiting the day of publication. The delay which has arisen since the first rough translation was completed two years ago has been due solely to the labour of revision. But the Gilbert Tercentenary does not occur till 1900, and the work will be published within a few months from the present date.—Yours, &c.,

SILVANUS P. THOMPSON.

Morland, Chislett-road, West Hampstead, N.W.

EARTHING THE MIDDLE WIRE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is to be hoped that the correspondence now going on in your paper on this subject will receive the attention it deserves. There are some very important aspects of the question which have not so far been touched upon by your correspondents. The rapid development of supply from central stations has introduced new elements which have not yet, it seems to me, received full consideration. There is a deep-rooted prejudice against earthing any portion of the circuit, and this prejudice is not without reason.

The reasons which have held against earthing on isolated installations apply with thousandfold force against earthing any portion of a general supply. They need not be recapitulated in detail here. They are based on bitter and dearly-bought experience, and are not to be lightly disposed of. They apply with almost equal strength to all systems of public lighting hitherto adopted, and they become stronger as the different parts of the work become, as they surely will, more and more dissociated. The time when the station, the underground conductors, and the house wiring were all done in whole or in part by one contractor is rapidly drawing to a close, and the skilled electrician will very soon be ousted from the detail work of wiring and fitting, which will certainly fall more and more into the hands of tradesmen, who will have to be entrusted with this department. Even now it is notorious that an "electrical engineer" is not necessarily even a skilled tradesman. It is therefore necessary to reconsider the whole question, keeping this important and inevitable new development in view.

The Fire Office rules have hitherto been of immense value in helping to secure fairly safe conditions—thanks to the attention of Mr. Musgrave Heaphy and other gentlemen who have followed in his footsteps, but it still remains for electrical engineers to provide a set of conditions under which the fire inspector may be expected to look after the interests of his company, and the tradesman to carry out his work, without expecting impossibilities of them in their respective spheres.

The experience of the past few years on American low-tension stations, where the almost universal practice is to earth the middle wire, is not at all encouraging. A very casual examination of the conditions will convince any experienced electrician that they are eminently unsatisfactory. Our experience on this side is likely to be quite as unsatisfactory.

Although it is not the general practice here to earth the middle or any other wire of set purpose, all the elements of danger exist in equal degree, so long as accidental earths may, as they certainly may, arise at any part of the circuit.

Hosted by Google

Electrical engineers are gaily proceeding with the laying of bare copper conductors in conduits where occasional, or even constant, leakage by earth connections is absolutely certain to take place. And the risk of such earth connections is by no means confined to low-tension circuits or to bare conductors. Every time such a fault occurs there are provided many thousands of conveniences for fire-making. On one side of every branch, every switch, safety-fuse, fitting and wire becomes a possible source of sparking to earth, and of fire. It is not a matter of surprise that the fire offices are alarmed at the prospect of such a state of affairs becoming normal and permanent by the wilful earthing of one of the conductors.

It would seem that the logical and right course is to admit at once the danger of earthing accidentally or on purpose, and to provide against it. This danger is really far more serious, as has been proved by the practical experience of many, than the danger of overheating of wires by putting too many lamps on.

Fortunately the cure is at hand with the disease. My friend Mr. Andrews has, as he says, nursed concentric wiring, and he deserves the thanks of the profession for his attention to the infant. There are now many others devoting their attention to its fuller development. Mr. Heaphy, on behalf of the Phœnix Fire Office, has so far recognised its existence as to embody in his rules provisions for carrying out work on this system. All danger of fire from electric light circuits disappears totally and for ever by the adoption of a continuous earthed metallic envelope forming the return conductor and completely enclosing, mechanically protecting and securing the "live" conductor at every point inside buildings from the supply mains or dynamo terminals to the lamp terminals; No part of the live conductor, whether switch, fuse, or other portion of the circuit, being exposed to possible contact with earth, the conductors being protected from overheating by fuses in the live conductor only. The outer conductor or envelope must of course be of equal or greater equivalent section than that of the live conductor.

The methods of discovering faults in underground conductors are many and easily applied, but it is impracticable even under the most favourable circumstances to remove the fault immediately it is discovered. With one wire earthed, the American method of discovering faults is also a method for removing them, and in conjunction with a concentric system of house wiring it is perfectly safe and certain. It is thoroughly practical and simple in application. Every leak causes a short-circuit; on a large station a short-circuit causes no interruption to the running of the plant, it simply causes a fall in E.M.F. More power is applied if necessary, and the fault is simply burned out. It is now considered unnecessary on a large station to use fuses in the distributing mains, because they are so much smaller than the feeders that the main itself acts as a fuse.

The connection of houses already "double-wired" to an earthed system is a serious difficulty, and therefore the system of "double-wiring" should cease to be applied as soon as possible. All bad work should be condemned by the supply companies or the Insurance inspectors, without fear or favour. A thoroughly sound job in double-wiring may safely be connected to an earthed system, earth being made only at the connection to the outside mains for convenience in testing, and all switches and fuses on the live circuit protected from possible earth contact. A daily test can then be quite simply made by connecting a single lamp of voltage depending on the size of the installation or a voltmeter, as a bridge between the earth connection and the circuit. The lamp will give a rough test of the goodness of the insulation, the voltmeter will give an exact test of its condition.

The safety of an installation depends more on the mechanical substantiality of the work than on guarantees of an imposing specification of hundreds of megohms per mile insulation resistance of the conductors. A rough surface on a sliding switch contract is more likely to cause fire than surface leakage from the body of the conductors. All such faults are rendered harmless by a complete concentric system.—Yours, &c.,

HENRY A. MAVOR.

THE PRICE OF ELECTRIC SUPPLY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to Dr. Hopkinson's proposed method of charging for electricity in Manchester, I believe I may claim to have been the first to suggest a scale of charges depending on the maximum current demanded by a consumer. The schedule of prices for the Electric Lighting Licence granted to the Liverpool Electric Supply Company in 1888 contained a sliding scale of charges per quarter, which may be shortly expressed as follows:—1st. For any number of units up to 100 times the number of units per hour of maximum demanded supply, 1s. per unit. 2nd. For any further quantity up to 100 times the maximum demanded supply per hour, 8d. per unit. 3rd. For any further quantity, 4d. per unit.

For example, a consumer demanding a maximum supply of three units per hour, and having used 1,100 units in a quarter, would be charged the following rates:—300 hundred units at 1s., 300 units at 8d., and the balance of 500 units at 4d.

It was found, however, that the consumers had some difficulty in understanding the scale, being accustomed to the sweet simplicity of the uniform rate charged by the local Gas Company, and that dissatisfaction was always expressed by consumers who used their lamps only a small number of hours, and, therefore, never reached the lower rates.

All sliding charges based on the maximum demanded supply have the serious disadvantage of limiting the number of lamps fitted up by a consumer to the smallest number he can possibly do with, thus preventing the adoption of the light in positions where the lamps are only occasionally required. A sliding scale is also an obstacle to the introduction of the light in buildings not often used, and especially churches, which are valuable customers to a supply company on account of only requiring a supply on Sundays, when the central station load is at a minimum.

Four years' trial of the above method of charging in Liverpool proved that its disadvantages were greater than its advantages, and consequently in the Liverpool Electric Lighting Order of 1892 the sliding scale was repealed, and a uniform rate of charge substituted. The present price charged in Liverpool is 7½d. per unit, or about double the price of gas, and with a rapidly increasing demand for electric light, and the more efficient and cheaper incandescent lamps that may be expected when the present oppressive monopoly in lamps comes to an end next year, the day is not far distant when the electric light will, in addition to its many advantages, be light for light as cheap as gas. A uniform rate has been found to answer well in the case of the greater number of Gas and Water Companies, and is equally suitable for Electric Supply Companies when the circumstances permit of a reasonably low price being charged.—Yours, &c., A. BROMLEY HOLMES.

Liverpool, December 5, 1892.

EFFECTIVE VOLTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: From your editorial comment on "Effective Volts" there seems to have been a certain ambiguity as to which definition of Dr. Thompson's was "precisely equivalent" to Dr. Fleming's. A little consideration will show that it was Dr. Thompson's definition of "effective," and not virtual (as mentioned by you), which was precisely equivalent to Dr. Fleming's definition of effective, *as referred to in his book*, and that Dr. Thompson's definition of virtual was identical with Dr. Fleming's effective, as defined in his present Paper. The main point I wish to contend is, that though granting that effective and virtual are identical in the special cases mentioned in the Paper, still they are only *special* cases, for effective as defined in the book is by no means necessarily the same as virtual; *e.g.*, if the current or effective E.M.F. were measured experimentally at every instant in the cycle as in Ryan's contact breaker experiments, the ordinates at any instant would represent effective E.M.F., but only that particular ordinate which had the value $1/\sqrt{2}$ of the maximum effective ordinate would be the virtual E.M.F. The intro-

Hosted by Google

duction of the word maximum in Dr. Thompson's definition of virtual was, of course, a slip on my part.

Trusting you will insert this in your next issue.—Yours, &c.,

Woolwich, December 2nd. ROLAND S. PORTHEIM.

THE DISSIPATION OF ENERGY IN HERTZ RESONATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I understand by a letter received yesterday from Dr. Bjerknes that two misprints crept into the account of his experiments in the *Comptes Rendus*. These are naturally repeated in your report (November 18th, p. 69), and perhaps you will kindly insert the following corrections:—

The period of oscillation should be $1{\cdot}4 \times 10^{-8}$ (not 14×10^{-8}). Four words are omitted from the last sentence, which should run: "That metals are more transparent to Hertzian undulations than to luminous undulations."—Yours, &c.,

County Offices, Stafford, Dec. 1, 1892. D. E. JONES.

PROF. AYRTON'S MAGNESIUM CELL AND HIS EXPERIMENTS ON THE MIGRATION OF GOLD THROUGH MERCURY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In closing the discussion of Mr. Swinburne's Paper on "Commercial Electrolysis" at the Institution of Electrical Engineers, the President, Prof. Ayrton, alluded to a subject of much general interest and one on which I should have liked to make a few remarks, had it not been contrary to the rules of the society. On reading the account of this discussion in your issue of November 25th I was reminded of the matter, and with your permission I will here recur to it.

In the first place, I must express my great satisfaction that Prof. Ayrton now admits that his former experiments, which led him to believe that an electric current could be generated by the action of one metal upon another, *e.g.*, the combination of magnesium with mercury, and which was directly opposed to my own results, were not trustworthy from want of the necessary precaution in carrying them out, and that the cell was truly a "sell," as the Professor himself jokingly remarked. I had previously demonstrated that the currents observed during the amalgamation of zinc, lead, tin, and cadmium, were due to changes of temperature, produced by the combination of these metals with mercury and their dissolution therein, and were therefore of thermo-electric origin, a result which was subsequently confirmed by other observers; consequently, it was difficult to understand why magnesium should behave in so entirely different a manner to other metals.

If I understood Prof. Ayrton rightly at the meeting, he stated that his results were due to the circumstance that the mercury was not quite cooled down when brought into contact with the magnesium, but surely this cannot possibly explain the high E.M.F., viz., 1·56 volts, which he obtained. According to Matthiessen the thermo-electric force between magnesium and platinum—which formed the other electrode of Prof. Ayrton's cell—is only about one-tenth of that of a thermo-electric couple consisting of copper and German silver, and for the latter I obtained 0·00014 volt for a temperature difference between the junctions of one degree centigrade. In order, therefore, to explain the observed E.M.F. exclusively by thermo-electric action, it would necessitate an enormously high temperature of the mercury such as is entirely out of the question. I believe the real cause of the high E.M.F. observed must be sought in quite another direction and is probably due to the introduction of a film of moisture or acid into the mercury along with the magnesium or platinum. It would be interesting to hear from Prof. Ayrton if he considers this possible or what other explanation he could suggest.

With reference to the experiment, also mentioned by Prof. Ayrton and which seemed to show the migration of gold through mercury by the action of the current, I venture to predict a fate similar to that of the magnesium cell when repeated with proper precautions. My own experiments with sodium dissolved in mercury and with various other liquid alloys did not show any signs of the transference of metals by the current, and the same result was subsequently obtained by several members of the Electrolysis Committee of the British Association. In my Paper, published in Poggendorff's Annalen in 1875 (supplement, Vol. VII., p. 280-312), I mentioned several instances in which a migration of metal had apparently taken place by the action of the current, but on closer examination I found it to be due to accidental causes. If a metal such as gold is placed on the surface of mercury contained in a straight vertical glass tube, its downward diffusion depends chiefly on the almost imperceptible circulation of the mercury in consequence of slight differences of temperature at various levels; any cause, therefore, which tends to increase this circulation, for instance, the accidental touching of the lower part of the tube with the warm hand, would, in all probability, accelerate the conveyance of small portions of the dissolved metal towards the bottom of the tube. This cause of disturbance could be overcome by the use of W-shaped tubes such as I employed for my experiments. An illustration of my apparatus was shown by Prof. Roberts-Austen in his Cantor lectures on alloys in the Society of Arts a few years ago, and is reproduced in his book on Metallurgy, p. 66.

As an apology for this somewhat lengthy letter I must plead the great interest attached to all experiments bearing directly upon our fundamental conceptions of the *genesis* of the electric current and the *modus operandi* of electrolysis.

—Yours, &c., EUG. OBACH.

Woolwich, Dec. 3rd, 1892.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As you have been so kind as to forward me a proof of Dr. Obach's letter of the 3rd inst., I am able to reply to it in this week's issue of *The Electrician*.

Dr. Obach says that he does not understand how an E.M.F. of 1·56 volt can be produced by a temperature effect in our metallic cell of magnesium-mercury-platinum, and he therefore suggests that a film of moisture, or of acid, may have been introduced into the mercury on the magnesium wire; but, so far from that, I think that it is possible that it was the very drying or the distilling of the mercury which led to the effect which Prof. Perry and I observed; for if a reference be made to our Paper, No. III., on "The Contact Theory of Voltaic Action," *Phil. Trans.* Roy. Soc., Part. I., 1880, and to my remarks made on the discussion of Dr. Lodge's Paper, "The Seat of the Electromotive Forces in a Voltaic Cell," it will be seen that apparent P.Ds. of as much as 3 volts are obtained between hot mercury and cold metals for a difference of temperature of only 20°C if the P.D. be measured inductively after the manner of Volta, Kohlrausch, Lord Kelvin, &c. And, as there stated, "The real explanation of the high potential difference and the abnormality of the results was that probably the main portion of the potential difference measured inductively was produced by an *invisible* film of oxide on the surface of the warm mercury, which possibly existed in spite of the fact that every effort was made to remove this oxide by distilling the mercury between every two sets of experiments," *Jour.* Soc. Tel. Eng. and Electricians, No. 57, Vol. XIV., 1885. The mercury I may mention was distilled at 350°C. in an iron still, for we had no vacuum mercury-still in Japan 15 years ago.

Our measurements with the magnesium-mercury-platinum cell were made with a quadrant electrometer, resistance, therefore, in the cell would not have affected the E.M.F. measurements, and, consequently, I have thought it possible that the E.M.F. of 1·56-volt may have been caused by the mercury and the magnesium wire being separated by a thin film of something which may have acted like an oxide, and by there existing a difference of temperature on account of the mercury not having been left long enough to cool down to the temperature of the room.

This possible explanation of the action of the metallic cell was not seen in 1877, since our experiments on hot and cold

Hosted by Google

mercury and on hot mercury and cold metals were not made until later.

In connection with this subject I may mention that a striking experiment can be made with a pair of platinum-copper junctions, one kept cool and the other placed in a flame. For if the wires at the hot junction be not very tightly twisted together, and the temperature be raised until the oxide plays on the copper wire, occasionally the junction between copper and platinum will be made through the oxide. Then instantly the spot of light of the electrometer rushes off the scale, indicating an E.M.F. of several volts.

As regards the electric transference of gold, Dr. Obach considers it impossible for a current passed through a vertical tube of mercury with gold at the top to have any effect in increasing the gold in the lower portion of the mercury; and he thinks that gold can only be carried down by thermal circuits. But surely if the electric current passing through the water into the mercury quickens the surface of the mercury, and so hastens the absorption of gold by mercury, it must gradually bring about the result of increasing the amount of gold in the mercury for some distance below the surface, even if there be no electrical transference in the true sense of the word.—Yours, &c., W. E. Ayrton.

December 6, 1892.

DYNAMO DESIGN.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your edition of October 21st I read with some amusement the abstract of an article entitled "Some Anomalies in Dynamo Design," and venture to trespass on your valuable space to comment on the same. The views expressed in this article would seem to be rather out of date. The construction of dynamo-electric machinery has got down to such a basis that a "trained engineer," or something very like it, is required to design machinery that will meet the demands of modern practice. Some years ago, when the speed was of no importance, when no one cared whether the temperature increased 10deg. or 100deg., or whether the regulation was within 1 per cent. or 20 per cent., in fact when about the only requirement was that the dynamo should give an electric current of about a certain amount, the "intelligent cow" did very well no doubt, but *nous avons changé tout cela*.

The best dynamos of to-day show good mechanical design, as they must, and this good "engineering" is expressed not only in the *bearings*, but in the general form, in the armature core, brush holders, commutator, &c., and also in the special tools used in construction; the latter, of course, do not appear outside the shops. The article goes on to make merry over heavy bedplates, and protests against dynamos so equipped being mounted on rails. It might have occurred to the critic that as it is necessary to put the dynamo on a sliding base instead of bolting it down to a foundation a heavy base is, *therefore*, required. In street railway work the sudden strains that are constantly being thrown on the belt require a good deal of weight to keep the machine steady and the base is certainly the place for it. In addition most of the modern dynamos have beds of box or turtle-back section which gives great rigidity without great weight, though they may look ponderous to the casual observer.

With regard to the unfortunate eye-bolt it might be said that as a dynamo is a most exceedingly compact machine, it can hardly be compared with a steam engine on the question of handling. For my part I see nothing unmechanical about the eye-bolt, and unless it is cast into the pole-piece, it is a question of taste or convenience whether it is left in the machine or stored away. Finally, it might be interesting to know what is meant by engineering as spoken of in this article.

If engineering consists solely in working out mechanical parts of mechanism, then I should say that the man who designs the form and proportions of a dynamo to give a certain output at given speed with given regulation, cost and space occupied, &c., has reached something above engineering. If such is the case, it would seem to follow that he has acquired the more elementary part and can be considered a "trained engineer" without doubt. It must be admitted, however, that the small mechanical details are often neglected, and it is not uncommon to find otherwise good machines giving no end of trouble, due to badly-designed brush holders or other minor parts. This shows the necessity for a thorough engineer on construction.—Yours, &c., F. V. Henshaw.

402, Greenwich-street, New York.

MR. HAUBTMANN'S GLOW-LAMP-TESTS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your journal (Vol. XXIX., pp. 573-590) you recently published Mr. Haubtmann's investigations on the efficiency and life of glow-lamps, which had originally appeared in the columns of *L'Electricien*.

Messrs. Siemens and Halske subsequently wrote a letter to *L'Electricien* correcting some points in the original article, and we shall be much obliged if you can find space in your journal for the enclosed translation of their letter.—Yours, &c., Siemens Brothers and Co. (Limited).

Alfred Sabine, Secretary.

London, S.W., December 7th, 1892.

[Translation.]

Berlin, November 8, 1892.

Mr. Ch. Haubtmann, Paris.

Although the article which you have published in *L'Electricien* for September 24 last does not show our glow-lamps to advantage, we thank you for having, in the public interest, raised so important a question, and for affording us at the same time the opportunity of publicly defending our interests.

You admit that our glow-lamps are carefully finished, but, according to the results of your experiments, their electrical qualities leave much to be desired. Yet these experiments are not free from criticism; on the contrary, we maintain that the results are due either to erroneous calculations or to faulty instruments.

We have made, and always continue to make, numerous experiments to satisfy ourselves that we keep the manufacture of our lamps at least as good as our competitors. Unfortunately we were not at liberty to publish in the technical journals the results of our observations, which are very widely divergent from your experiments.

Our French and English competitors might have found that wrong on our part, and very justly, for they would have had the right to reproach us for attempting to injure their interests by an *oratio pro domo*. You remove our scruples by calling us publicly forward yourself.

Before entering on a criticism of your figures, we desire to inform you that the French and English markets are at present closed against our lamps on account of the Edison-Swan patents, but, on the comparatively early expiration of these patents, we intend to compete with the French and English manufacturers. It is, therefore, of primary importance for us to at once remove the bad impression which your article may have produced on the public respecting our glow-lamps.

We go on now to your experiments:—

1st. "The lamps of 'La Française,' 16 c.p., 102 volts, 2·98 watts per candle-power, would require 3·6 watts per candle-power at a pressure of 110 volts."

May we be permitted to tell you that this is simply impossible; for, by increasing the normal pressure of a glow-lamp, the light increases much more than in the simple proportion of the pressure and current. Therefore, in place of an increase, there will be a decrease in the absorption of energy per candle-power if the normal pressure be exceeded.

2nd. "The Siemens lamps would require 2·81 watts per candle-power at a pressure of 102 volts; 2·70 watts per candle power at a pressure of 110 volts.

This is far from being correct. According to the statements of the Physical Technical Institute of the German Empire at Charlottenburg, the authority of which on such points you will scarcely impugn, the Siemens lamps of 16 c.p., 102 volts, 2·81 watts per candle-power, take only 2 watts per candle-power at 110 volts.

3rd. "The absorption of energy per candle-power in the Gabriel lamps of 10 c.p., 102 volts, would be 2·1 watts per candle-power at the beginning, would rise to 6 watts per candle-power after 250 hours, to fall again to 4·9 watts per candle-power after 500 hours."

This change can only be explained by the circumstance that the one lamp which remained after the 500 hours was necessarily much superior to the other lamps of the series as regards the constancy of the emission of light. But in that case, this series could not give a correct idea of the average of the Gabriel lamps, and it would have been better to have omitted it from your article.

We will not continue, though there are many other points on which we might touch. It is enough that we have protected our own interests without impinging on those of our French and English competitors, by showing that the results of your experiments can in no way be considered as decisive, and that they leave the merit of our lamps untouched.—We are, &c. Siemens and Halske.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The Urban Sanitary Authority of Portsmouth invite tenders for the supply and erection of boilers, steam engines, condensers, steam and water pipes, pumps, overhead hand-power traveller, electrical machinery, apparatus, &c. Tenders must be delivered to Mr. Hellard, town clerk, not later than 6 p.m. on January 5, 1893. Further particulars appear in our advertisement columns.

TENDERS RECEIVED.—The following tenders have been received by the London County Council for the electric lighting (contract No. 2) of Claybury Asylum :—

Bourne and Grant	£14,400	0	0
J. D. F. Andrews and Co.	12,560	0	0
Fowler, Lancaster, and Co. (Limited)	11,780	0	0
H. Binko and Co.	10,999	10	0
Electrical Supplies and Fittings Co. (Limited)	10,300	0	0
Roger Dawson	9,887	0	0

TENDERS ACCEPTED.—The Bristol Urban Sanitary Authority have placed the contract for supplying the whole of the condensing plant for their large electric light installation with Messrs. W. H. Allen and Co., who, owing to the contract having been previously placed in other hands, are called upon to complete the work within a very short period.

——— The offer of Messrs. Lowden Brothers for the execution of the work in connection with the electric lighting of the Reading Rooms and Merchants' Exchange at Dundee has been accepted by the Dundee Chamber of Commerce.

——— The Stepney Guardians have accepted the tender of Mr. Flynn to establish telephonic communication between the doctor's house and the workhouse at a cost of £15 and £2 annual maintenance.

SALES BY AUCTION. — Messrs. Wheatley Kirk, Price and Goulty have now ready the catalogue of the modern engineering and electrical fixed and loose plant, fittings, &c., which are for sale on Tuesday next, the 13th inst., at the Eastdown Works, Dermody-road, Lewisham, S.E. The catalogue includes several fly screw presses, lathes, shaping, milling, and drilling machines, electric motors and dynamos of the Gill, Elwell-Parker, Siemens, Brush-Victoria, and other makes, measuring instruments, electric light standards, gas and steam engines, accumulators, and a large quantity of miscellaneous plant and material. The sale commences at 10 for 11 prompt.

DISSOLUTION OF PARTNERSHIP.—Messrs. Cremer and Cheeld, carrying on business at Chesham, Bucks, as electrical and general engineers, have dissolved partnership, debts being paid and received by Mr. Sydney Cheeld.

REMOVAL NOTICE.—Messrs. Gwynne and Co., Hydraulic and Mechanical Engineers, have removed from Essex-street Works, Strand, W.C., to larger premises at Brooke-street Works, Holborn, E.C.

MESSRS. J. S. LEACH AND CO.—This firm send us circulars dealing with the specialities manufactured by them, including electric telephones and bells and electric lighting plant and apparatus, and also drying machines, shafts and shaft fixings, pulleys, steam pipes, air propellers, patent ventilators, fly-wheel guards, street and door lamps, watchmen's lamps, &c.

MESSRS. PYKE AND HARRIS.—This firm have several important lighting installations in hand, amongst these being one for Lord Montagu at Queen's-gate, London, W., and another at 47, Gloucester-terrace, Hyde Park.

MESSRS. RASHLEIGH PHIPPS AND CO.—This firm are carrying out the lighting of the new premises of the Star Life Assurance Company in Moorgate-street, and also the premises recently taken by Messrs. Elkington and Co., the well-known silversmiths, in Cheapside.

MR. ROGER DAWSON.—The electric light fittings used in the extensive electric light installation at the Junior Constitutional Club's new premises in Piccadilly were, we are informed, specially designed and manufactured by Mr. Roger Dawson.

APPOINTMENT.—Mr. Joseph A. Jeckell, who was recently appointed electrician to the International Okonite Company (Limited), has, we understand, been appointed manager of the Company's works at Newton Heath, Manchester.

ELECTRIC LIGHT V. GAS IN CITY OFFICES.—The Directors of the National Safe Deposit Company decided in November, 1891, to introduce the electric light in their large underground offices and vaults at Queen Victoria-street, E.C., which comprise three floors or vaults below the surface of the street. It is absolutely necessary that the corridors in which the safes and strong-rooms are situate should be well lighted, and complaints had previously reached the Company from renters and depositors that the lighting was not efficient. The Company's staff also were frequently invalided owing to the vitiated atmosphere in which they were compelled to work. An attempt was first made to improve matters by the introduction of the most approved gas arrangements, and this resulted in a considerable saving of money, but in only a slight mitigation of the ill effects of the gas; and in consequence, the electric light was, in February, 1892, substituted over the greater part of the premises, with the result that the staff and customers have greatly benefited in health, and a saving of 10 per cent. upon the reduced gas bill has been effected, after allowing interest on the original outlay for plant (about £500) and for depreciation, repairs, and renewals. The two 28-H.P. engines used are those originally supplied for the lifts and the air and water pump. The manager of the Company, Mr. J. S. Wilkes, expresses the greatest satisfaction with the results obtained, which represent an actual saving on the original gas lighting bill of about 30 per cent.

ARBITRATION.—It has been decided to form Chambers of Arbitration, similar to that recently formed in the City of London, at Edinburgh, Cardiff and Sheffield.

CALENDARS FOR 1893.—Messrs. STREET AND CO., the well-known advertisement contractors of Cornhill, E.C., send us a neatly-framed Calendar for 1893.——The ANGLO-AMERICAN TELEGRAPH COMPANY issue a useful hanging Calendar Pad for 1893, of neat design.

ASTON.—The Aston Local Board has received from its Highway Committee an intimation that it has under consideration the desirability of adopting the electric light in lieu of gas, and hope to shortly report fully on the matter. The success and popularity of the large electric installation at the new bath had induced the Committee to take this matter into consideration, and the Surveyor has received instructions to make inquiries and get together all the information in view of the early discussion of the subject.

BELFAST.—Following on a series of interesting articles on Electric Lighting which appeared in the *Belfast Evening Telegraph*, the proprietors of that journal are to be congratulated on the "discovery," through an interview by one of their representatives with a Mr. Gallaher, of a marvellous method of reducing the first cost of electric lighting; and, more important still, bringing this improved state of affairs about by the aid of the electric light's arch enemy—gas. According to Mr. Gallaher, a Mr. Harris, of America, has invented an apparatus by which 10lb. of coal produces about 700 cubic feet of gas, and the addition of two gallons of crude oil raises this amount to over 1,000 cubic feet. By doubling the quality of oil the fuel gas can be carbonated up to any desired candle-power, and can, therefore, be used for illuminating as well as for heating purposes, at a price which, with coal at 10s. per ton, and crude oil at 3s. 6d. per barrel, represents gas at 2½d. per 1,000 cubic feet. By means of this cheap fuel gas, electricity is to be supplied at such a cheap rate that all lighting methods will be revolutionised. Mr. Gallaher says that he has seen 110 incandescent lights burn for ten hours at a total cost of 9d., the generating plant being a gas engine consuming fuel gas made on the premises. Mr. Gallaher further states that the process has been introduced in Washington, Maysville, Connorsville, and other towns in the United States. Query, Is this "discovery" any advance on the Dowson process? It is, perhaps, as well to add that Mr. Gallahar, whose offices are situated in York-street, Belfast, entirely controls the patents of this apparatus for the United Kingdom.

——— On Friday last Prof. Kennedy, in his capacity of consulting engineer to the Belfast Corporation, examined the plans of the district with the object of advising the best system of electric lighting to be adopted by the City authorities. He will shortly present his report.

BOGNOR.—The Board of Trade have intimated to the Local Board that having received no further communication on the subject of the Electric Lighting Order of 1890, they propose to revoke the Order forthwith.

BRISTOL.—The *Bristol Times and Mirror* states that about a dozen firms have sent in tenders for the distributing mains for the Bristol lighting, including, at least, one local firm of contractors whose business usually lies in building operations. The estimates vary from between £14,000 and £15,000 to something over £25,000

Hosted by Google

The Electrical Committee have referred these tenders to Mr. W. H. Preece, consulting engineer to the Corporation, and upon receipt of his report will select the tender most nearly complying with the conditions imposed. With reference to the erection of a central station a small sub-committee has been appointed to watch the building operations, which are expected to be completed in September next.

CHAGFORD.—A curious state of affairs has come to pass in this town. For some time past the citizens could select either gas or electric light for their illuminant, but the Electric Light Company having recently succeeded in obtaining their Order for lighting the town, the Directors of the Gas Company decided either to sell the gas works or close them altogether, the result being that Mr. Willey, of Exeter, has purchased these works for £150, and took possession last week. It now remains to be seen which illuminant will survive the ordeal of acute competition.

CHELSEA.—The surveyor to the Chelsea Vestry has presented his report on the subject of the electric lighting of the district, and it has been decided to print the report for distribution amongst the members of the Vestry.

CHICAGO SOUVENIR.—The Bubier Publishing Company, of Lynn, Mass., forward us an illustrated sheet calendar for 1893, giving twelve views (one for each month) of the Chicago Exhibition buildings.

COVENTRY.—The Town Council on Tuesday had under discussion the future of the local tramways. Last year the time allowed for the continuance of the old system of steam expired, and since then the trams have not been allowed to run through the centre of the city. The line has been bought by Mr. Graff Baker, who is endeavouring to get Coventry to consent to overhead electric wires. A deputation went to inspect the Roundhay tramway at Leeds at his invitation, and came back satisfied. An official depuation, however, who also visited Leeds, as well as Walsall, now recommended the Council not to consent to the adoption of the Thomson-Houston system. A proposition to this effect having been moved, a long and exciting discussion arose, and it was finally adjourned to allow of an inspection of a sample overhead wire, which Mr. Graff Baker is going to erect in Hertford-street.

DERRY.—Opposition is to be offered to the proposal of the Derry Corporation to borrow £40,000 for electric lighting purposes.

DUDLEY.—The Borough Surveyor has been instructed to obtain all particulars with regard to electric lighting with a view to its adoption by the Town Council who have a dispute with the local Gas Company.

DUNDEE.—The first of the large boilers which are being made by Messrs. Whyte and Cooper for the Electric Lighting Station underwent a critical test last week, with satisfactory results. It is expected that four out of the six Willans and Robinson's engines which are selected for the installation will be delivered this week. These engines indicate 135 H.P., the remaining two being 60 H.P.

——— With regard to the lighting of Dundee, some considerable extensions have been agreed to, and the scale of meter rents has been prepared as follows:—10-ampere meters—Ferranti, £6; Aron, £6. 15s.; Kelvin, £8. 10s. Meter to be used—Ferranti; rent at 12½ per cent. = 15s. per annum, say, 4s. a quarter. 20-ampere meter—Ferranti, £6. 15s.; Aron, £6. 15s.; Kelvin, £8. 10s. Meter to be used—Ferranti or Aron; rent at 12½ per cent. = 16s. 3d. per annum, say 4s. 6d. per quarter. 30-ampere meter—Ferranti, £7. 10s.; Aron, £6. 15s.; Kelvin, £8. 10s. Meter to be used—Ferranti or Aron; rent at 12½ per cent. = 18s. 9d. per annum, say 5s. a quarter. 40-ampere meter—Ferranti, £8. 10s.; Aron, £6. 15s.; Kelvin, £8. 10s. Meter to be used—Aron or Kelvin; rent at 12·5 per cent. = 21s. 3d. per annum, say 5s. 6d. a quarter. 50-amperes (Kelvin), 6s. a quarter. 60-amperes (Kelvin), 7s. a quarter.

ELECTRIC HEATING AND COOKING.—A series of lectures was delivered last week at Hove, Sussex, by Mr. H. J. Dowsing (of Messrs. R. E. Crompton and Co.), on the subject of "Electricity for Domestic Purposes." The lectures were received with applause, and owing to the fact that there are three electric supply stations in the district, it is anticipated that before very long a good day load will be the outcome of the interest which they have been successful in arousing.

FALMOUTH.—In view of the early adoption of the electric light for the town of Falmouth the Lighting Committee of the Urban Sanitary Authority recommend that no further gas lamps be purchased.

IRVINE.—At a meeting of the Town Council on Tuesday night it was proposed that the Town Council appoint an electrical engineer to inspect the Town Mill, and report as to whether by fitting up a turbine water-wheel motive power could be got sufficient for the lighting of the streets and harbour by electricity. The matter was referred to the Town Council in committee.

JOHANNESBURG LIGHTING.—The *Cape Argus* states that the £35,000 Debenture issue recently offered for subscription by the Johannesburg Lighting Company have been placed in London at par, and that the Company will therefore have this additional capital at its disposal, enabling the Managing Director to supply either gas or the electric light for the whole of the township and suburbs.

KINGSWOOD.—A complaint was made at the last meeting of the Kingswood Local Board of the indifferent lighting of the streets by the electric light, and it was resolved to inspect the whole of the lighting area and report. A meeting of the Ratepayers' Association was also held, at which the terms of the contract between the Local Board and Messrs. Parfitt and Son were discussed, and it was pointed out that if Messrs. Parfitt and Son gave no better light than the gas there would still be a saving to the ratepayers on the contract with that firm. It was ultimately decided to call upon the Local Authority to deal promptly in the matter.

LA PLATA.—A trial of the electric tram cars at La Plata was recently made, and proved a success. A number of railway and tramway managers will shortly meet and inspect the working of the cars.

LIVERPOOL.—Permission has been granted to the Liverpool Electric Supply Company to put down mains in Sefton Park to supply the houses on Corporation property whose tenants desire to substitute the electric light for gas.

MANILA.—An Electric Lighting Company, with a capital of $500,000 in $25 shares, has recently been established at Manila, where in the course of a few months it is expected that the city will be lighted throughout by electricity.

MONEYMORE, IRELAND.—The *Belfast Morning News* understands that a scheme is on foot for lighting Moneymore by electricity.

OMNIBUS LIGHTING.—The London General Omnibus Company are reported to be lighting the whole of their omnibuses with electric lamps, the "Favourites," all running to the North of London, having already been fitted with the light, which is in the centre of the roof, the batteries being placed under the seats.

READING.—At the last meeting of the Town Council the question of lighting the large Town Hall by electricity came under discussion. It should be stated that a sub-committee had been appointed to take prompt measures in the matter of lighting the Town Hall by electricity, owing to the fact that the timbers in the roof had been seriously affected by the gas. The sub-committee now recommended that in view of the probability of the Reading Electric Supply Company (Limited) being at an early date in a position to supply electric current for lighting the Town Hall, no further steps be taken in the matter, but that the roof be painted near the gas jets with asbestos paint, and be provided with shields. The question of opposing the Reading Electric Supply Company's obtaining a Provisional Order for lighting the town has also been discussed by the Town Council, and the Lighting Committee have, in conjunction with the representatives of the Company, arrived at a draft agreement, which the Committee will recommend the Council to accept.

REDRUTH.—This town is shortly to have an Electric Supply Company, and the promoters, before issuing the prospectus, are endeavouring to form some estimate of the support they are likely to receive from the Redruth public both as shareholders and consumers. The capital is £10,000 in 500 Five per Cent. Preference Shares, and 1,500 Ordinary Shares of £5 each. The Company have selected the low-pressure three-wire system, the central station being situated at Pednandrea.

ST. HELEN'S.—A Sub-Committee of the Gas and Lighting Committee of the Corporation has been appointed to consider the question of providing for the supply of electricity within the borough.

SAN JUAN (ARGENTINA).—This city will shortly be lighted by electricity.

STAFFORD.—At the Town Council meeting on Tuesday the report of the Electric Lighting Committee recommending the Council to take active steps for the provision of electric light for the borough was presented. It states that the Council has a capital of £100,000 bound up in their monopoly of the gasworks, and that the period for which the provisional order for electric lighting was granted to the Corporation having expired, a private company would step in unless the Corporation took immediate action. The cost of an installation of 3,000 lights would be £20,000; it would require 2,000 lamps to make the thing pay; and with the County Council, the Post Office, and private consumers who were already prepared to take the light, there was reason to believe that 1,500 lamps would be taken from the start. The effect on the consumption of gas, even if 3,000 lamps were supplied, would be but the slightest, and the monopoly of the Corporation would be preserved. The report was adopted.

Hosted by Google

STUDLEY.—The electric light has been introduced into Messrs. W. Hall and Company's Needle Works at Studley, and provision has been made for driving the machinery in addition to lighting.

TEIGNMOUTH.—At a meeting of ratepayers held on Wednesday, the Chairman said that two schemes had been placed before the Local Board for the extension of the gasworks, the cost of one being £16,000 and the other £10,000. Two schemes of electric lighting had also been before the Board at a cost of £8,500 and £15,000 respectively. In order to make the introduction of the electric light pay itself, it would be necessary that there should be 900 lamps taken up by private consumers. After a short discussion, a deputation was appointed to confer with the Local Board on the question.

THETFORD.—At the meeting of the Board of Guardians last week, in advocating the use of the electric light in the workhouse premises, Mr. Oldman said he had used that illuminant in his residence for 18 months, and that it had proved better and much cheaper than gas. It was therefore decided to obtain an estimate.

THE SMITHFIELD CLUB SHOW.—The annual show of the Smithfield Club was held at the Agricultural Hall, London, during this week, and amongst the exhibitors were :—Messrs. Marshall, Sons and Co. (Limited), of Gainsborough ; Messrs. Robey and Co., of Lincoln ; Messrs. John Fowler and Co., Leeds (Limited) ; Messrs. Clayton and Shuttleworth, of Lincoln ; Messrs. Crossley Brothers (Limited), Openshaw, Manchester ; Messrs. Ransomes, Sims and Jefferies (Limited), of Ipswich ; Tangyes (Limited), Birmingham ; Messrs. Ruston, Proctor and Co. (Limited), Lincoln ; and other well-known agricultural and general engine and machinery builders. Messrs. Ransomes, Sims and Jefferies' exhibits include a 10-H.P. long-stroke engine, with the main frame in one casting, and all parts interchangeable for either hand. Messrs. Robey and Co.'s extensive exhibit includes a special vertical high-speed engine for electric lighting, fitted with lubricated arrangements for continuous running. Messrs. John Fowler and Co. have an 8-H.P. horizontal engine on show, which is specially constructed for economical working in electric lighting installations, and are made for both right and left-hand working ; and on Messrs. Clayton and Shuttleworth's stand is a fine specimen of the compound under-type engine, for which this firm claim many advantages. Messrs. Marshall, Sons and Co. occupy a large space in the exhibition, and have, in addition to some fine examples of their agricultural machinery, several engines on view made with special regard to the requirements of lighting and power installations. Messrs. Ruston, Proctor and Co.'s stand includes a "U"-type vertical engine, fitted with a sensitive governor and a convenient speed adjuster. A large number of these engines have been included in lighting plants all over the country. In gas engines Messrs. Crossley Brothers had several examples on show, and it is only necessary to mention that the engines exhibited possess all the latest improvements which have made this firm's engines so well known in electric lighting circles. Tangyes (Limited) have also on view some fine specimens of their gas engines, including a 12 H.P. engine of the very latest pattern. Another class of engines which is gradually coming to the front at the Smithfield Shows are the oil engines, and Messrs. Priestman and Co. have several very compact machines on view. We are unable to chronicle that any progress has been made with the electric lighting installation at the Agricultural Hall, notwithstanding that at such a Show as that held this week the advantages of the brighter and cooler illuminant would have been obvious.

WEST BROMWICH.—The Town Council on Wednesday had under consideration a recommendation of the Estates Committee that they should be authorised to obtain specifications and tenders for lighting the Town Hall, corridors, ante-rooms, municipal offices, &c., also the free library, with electricity, and to provide such a plant for this purpose that, if thought desirable, the institute could be also lighted by the same means. In the event of the recommendation being adopted the committee propose to obtain a separate tender for the institute, so that the cost of both schemes could be ascertained, and one or both be adopted. The estimated cost was £1,720. After some discussion, the Council decided to postpone the matter for twelve months.

WESTMORELAND.—Leave has been granted to Messrs. R. H. Fell and Son (Limited) to put electric light cables under certain of the main roads at a rent of 10s. per mile per annum.

WHITTINGHAM.—At the last meeting of the Lancashire Asylums Board it was proposed to grant a sum not exceeding £450 for the lighting of the grounds of the Whittingham Asylum by electricity.

WOLVERHAMPTON.—The Committee will, we understand, recommend the Wolverhampton Town Council on Monday to accept the tender of the Electric Construction Corporation (Limited) to instal the electric light within the portion of the borough decided upon by the Council. The cost of the work will be about £28,000, exclusive of the cost of buildings which will be necessary for the machinery and other plant.

WORCESTER.—At a meeting of the City Council, on Tuesday, the Watch Committee recommended the Council to obtain a loan to purchase the Powick Mills and the land adjoining for the sum of £5,000, for the purpose of a generating station for electric lightiing and to enter into a contract with the Brush Electrical Engineerng Company (Limited), for the work in connection therewith, the total expenditure amounting to £31,000. An amendment was moved that the question should be referred to the Committee for further details to be furnished ; but after considerable discussion the original recommendation was adopted.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

November 11, 1892.

20,360. R. A. GOODMAN. Halifax. Improvements in electric arc lamps.
20,371. A. G. BURRELL. Sheffield. Automatic electric railway signal.
20,415. J. T. GENT, A. W. STAVELEY, and J. H. PARSONS. London. Improvements in microphones.

COMPANIES' MEETINGS & REPORTS.

Morecambe Electric Light and Power Company (Limited).

In the report of this Company just issued the Directors congratulate the shareholders on the successful establishment of the Company's installation and its profitable working. The consent of the Board of Trade to proceed with the works was only given in March 12th last, thus greatly limiting the time in which to get down the plant for season business. Notwithstanding, cables were laid in thirteen streets, and the work was so efficiently done as to preclude any appreciable leakage.

The demand for service being much in excess of the provision made (which was based on the subscribed capital), the Directors found it requisite to make additions to the generating plant forthwith ; and as the season advanced a full load was obtained. These additions are not yet covered by subscribed capital, and will continue to absorb a portion of the profits which would otherwise be available for increased dividend. Now that the soundness and profitable character of the undertaking is demonstrated, shareholders should have no hesitation in availing themselves of the opportunity of adding to their holdings at par.

Hosted by Google

As to depreciation, a considerable portion of the plant is under guarantee for first year ; and the "Dowson" gas-making apparatus and necessary building were only completed in October. For the remainder of the plant, in view of the short term during which it has been in use, the item would be inappreciable, and is therefore waived. A sum of £16. 3s. is, however, written off formation expenses, which stand at a low figure. The gross profit of £74. 9s. 11d. is reduced by £22. 6s. 7d. for interest on borrowed capital, leaving a balance of £50. 12s., which the Directors recommend to be applied to the payment of a dividend at the rate of 5 per cent. per annum on the called-up paid share capital. Shareholders will be pleased to learn that important extensions of the service are now in progress, and further extensions are contemplated in the Spring. The retiring Director (Mr. Farrar) is eligible, and offers himself for re-election. The auditor (Mr. Duff) also offers himself for re-appointment.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

EDISON-BELL PHONOGRAPH CORPORATION (LIMITED).—This Company was registered on November 30th with a capital of £60,000 in £5 shares. The objects are—to enter into and carry into effect an agreement with the Edison United Phonograph Company, of New Jersey, U.S.A. ; to apply for, obtain, or otherwise acquire any inventions, letters patent, licences or concessions for, or in relation to, phonographs and graphophones, telephones or any combinations thereof, for the recording and reproduction of speech and other sounds, and for, or relating to, any machine, instrument, or apparatus for recording or reproducing speech or other sounds by means of electricity or other means or connected with the generation, utilisation, storage, accumulation, distribution, transmission and employment of electricity, and to carry on the business of manufacturers of and dealers in and contractors for the sale, supply, letting on hire, erection and maintenance of phonographs, graphophones, telephones, phonogram cylinders, tablets, diaphragms, motors, batteries, generators, magnets, cylinder coverings, &c., or to trade as electricians, mechanical, electrical, chemical and general engineers, iron, brass and metal founders and manufacturers, dealers in and contractors for the supply of electricity or other power agency or energy. The subscribers are :—

	Shares.
William A. Smith, 6, Hanover-street, Glasgow	1
F. Faithfull Begg, Bartholomew House, E.C.	1
Charles A. Hanson, 49, Holland-park, London, W.	1
D. Johnstone Smith, 149, West George-street, Glasgow	1
S. H. Sands, West Hill House, Lenton, Nottingham	1
Edward F. Coats, 99, Gresham-street, London, E.C.	1
C. Morrison, 53, Coleman-street, London, E.C.	1

The number of Directors is not to be less than three nor more than eight, the first being F. Faithfull Begg, W. T. Coats, D. Johnstone Smith, and William A. Smith. Two additional Directors will be appointed by the Edison United Phonograph Company of New Jersey, U.S.A. Qualification: £1,000 nominal value.

LANDORE COPPER COMPANY (LIMITED).—This Company has been registered with a capital of £3,000, in £1 shares, to carry on the copper smelting and manufacturing works at Landore, near Swansea, now being carried on by Mr. Thomas Elford.

LOCKE AND CO. (LIMITED).—Mechanical, electrical and general engineers. Capital, £1,000, in £1 shares.

WALSALL ELECTRICAL COMPANY (LIMITED).—This Company was registered on December 6th, with a capital of £10,000, in £10 shares. The objects are to acquire and take over as a going concern the business of a manufacturing electrician and electrical engineer, now carried on by Frederick Brown, at Walsall, in the County of Stafford and at Birmingham, under the style or firm of "The Walsall Electrical Company," with a view thereby to enter into and carry into effect an agreement with the said Frederick Brown to manufacture, provide, sell, deal in, and let for hire engines, dynamos, machinery, wires, lamps, telephones, instruments, fittings, &c., and to carry on the business of electricians, electrical engineers and contractors, mechanical and general engineers, iron and brassfounders, suppliers of electricity, and manufacturers of and dealers in all things required for or capable of being used in connection with the generation, supply, accumulation, distribution, and employment of electricity. The first subscribers are—

	Shares.
John Hildick, junior, Mellish House, Mellish-road, Walsall	1
Henry P. Nichlin, The Elms, Rushall-road, Walsall	1
Joseph N. Fellows, 44, Bradford-street, Walsall	1
Frederick Brown, Fairy Field, Highgate, Walsall, electrical engineer	1
Samuel Beebee, East View, Sutton-road, Walsall	1
Thomas H. Fellows, 88, Corporation-street, Walsall, electrical engineer	1
William Beebee, 4, Wolverhampton-street. Darlaston	1

The number of Directors is not to be less than three nor more than five.

"DROSOPHORE" COMPANY (LIMITED).—This Company has been registered with a capital of £15,000, in £5 shares, to acquire certain rights from Messrs. Kleiner, Bockmeyer, and Co., of Moedling, near Vienna, and to manufacture and deal in apparatus and machinery for ventilating and for warming, cooling, drying, moistening, and disinfecting the atmosphere.

UNITED KINGDOM ECONOMIC GAS SYNDICATE (LIMITED).—This Company has been registered with a capital of £10,000, in £1 shares, to enter into an agreement with A. W. Wells, and to carry on the business of gas, mechanical, electrical, chemical, and general engineers, &c.

ALLCHIN, LINNELL, AND CO., LIMITED (in Liquidation).—Proofs of debts must be sent in to the Official Liquidator, Mr. C. J. Stewart, 33, Carey-street, E.C., by the 17th inst.

LIRONI AND BOWMAN (LIMITED).—An agreement, dated October 12th, between Vittorio G. Lironi and John J. Bowman, of Bow Electric Works, Arnold-road, Bow, London, E. (called the "vendors"), and this Company states that the Company agrees to purchase the goodwill, plant, machinery, stock-in-trade, &c., of the business of electrical engineers carried on by the vendors at the Bow Electric Works, and also the following patents belonging to the vendors :—Provisional patent No. 14,527 (1891), No. 19,554 (1891), and No. 19,553 (1891). The consideration was £1,200, and was fully satisfied by the allotment of 1,200 fully paid-up shares of £1 each, such shares not being transferable for seven years without the consent of six-sevenths of the shareholders. Another agreement of the same date between Thomas W. Hollington and Alfred J. Hollington (called the vendors) and this Company states that the Company agrees to purchase certain plant, machinery, engines, tools, &c., in or about the Bow Electric Works, for £1,200, £800 of which was to be paid in fully paid-up shares of £1 each, and £400 by the issue to the vendors of debentures, part of an issue not exceeding £1,200. The statutory return, made up to November 25th, has been filed. Out of a capital of £2,000, in £1 shares. all the shares have been issued as fully paid.

LITHANODE AND GENERAL ELECTRIC COMPANY (LIMITED).—The statutory return of this Company made up to November 17th has been filed. The Company is a reconstruction of the Mining and General Electric Lamp Company (Limited), and bought the patents of the said Company, and in consideration therefor allotted or agreed to allot 91,500 shares, each considered as having 16s. paid, to the shareholders of the old Company, according to their interests. At the time of making up, 17,725 shares had been taken up, each of which had been issued with 16s. considered as paid. A call of 2s. per share had been made, resulting in the payment of £998. 3s., and leaving £974. 7s. in arrears.

LONDON CARBONS MANUFACTURING COMPANY (LIMITED).—This Company is to be wound up by the Registrar of Joint Stock Companies.

LONDON ELECTRICAL TRAMWAYS COMPANY (LIMITED).—This Company is to be wound up. The Company was registered on April 22, 1891, with a capital of £150,000, in £1 shares, to acquire and carry on the system, equipment, and undertaking of the North London Tramways Company.

NORTH-EASTERN TELEPHONE COMPANY (LIMITED).—At meetings of this Company held on November 10th and 29th, resolutions were passed and confirmed that the Company be voluntarily wound up, and that Mr. T. D. Challoner, 33, Mosley-street, Newcastle-upon-Tyne, be the liquidator.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended December 4th were £907, as against £810 for the corresponding period of last year, being an increase of £97. The total receipts for half-year amount to £18,807, against £16,983 in the corresponding period of 1891, being an increase of £1,824.

COMMERCIAL CABLE COMPANY.—The Directors have declared a quarterly dividend at the rate of 7 per cent. per annum, payable on the 2nd prox. It has also been decided to redeem £120,000 of the outstanding debenture bonds on the 15th prox.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of November were £3,200, as compared with £3,263 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the month of November were £2,137, against £2,335 for the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of November amounted to £60,491 and to £60,053 in the corresponding period of last year, an increase of £438.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of November, 1892, amounted to £40,851, and to £40,686 in the corresponding period of 1891, or an increase of £165.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for November amounted to £22,000, and from January 1st to November 30th to £245,600. In the corresponding months of 1891 and 1890 the amounts were £260,200 and £256,400 respectively.

NATIONAL TELEPHONE COMPANY (LIMITED).—The Directors declare interim dividends for the half-year ended October 31, 1892, as follows :—First Preference Shares at the rate of 6 per cent. per annum, less income-tax ; Second Preference Shares at the rate of 6 per cent. per annum, less income-tax ; Third Preference Shares at the rate of 5 per cent. per annum less income-tax. On 90,950 shares (£3 paid) numbered 1 to 90,950 upon the amounts paid up from the dates of the respective calls, and on 28,284 shares (£5 paid) numbered 90,951 to 119,234 from September 27, 1892 (ordinary shares) at the rate of 5 per cent. per annum, less income-tax.

Hosted by Google

RICHARD HORNSBY AND SONS (LIMITED).—The ordinary general meeting of this Company was held on Monday last at the Cannon-street Hotel, E.C., Mr. James Hornsby, J.P., D.L., presiding. The Chairman regretted that the Directors were unable to recommend a higher dividend, although the earnings of the Company were larger than in the previous year, but owing to the severe competition in many branches of the engineering trade, coupled with the fact that labour was so much more costly, profits had been cut down. He reported a good business with the Hornsby-Akroyd oil engine, which had been greatly improved and recently placed upon the market. A dividend of 2s. 6d. per share was agreed to.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Dec. 2, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,185.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts for the two weeks ended November 30th were £2,338, as compared with £2,336 for the corresponding period of last year.

SALES BY AUCTION, &c.

IPSWICH.—On MONDAY, 19th December, 1892, at 12 o'clock precisely.

GARROD TURNER and SON will SELL BY AUCTION, by direction of the Sheriff of Suffolk, the ELECTRIC LIGHT PLANT of the IPSWICH ELECTRICITY SUPPLY COMPANY, at 31, Carr-street, including a 14-H.P. Portable Steam Engine by Ransomes, Sims and Jefferies; two 200 light shunt Dynamos; sixty glass Accumulators; Incandescent Lamps; Ammeters, Voltmeters. Motors, and the various accessories for electric lighting. Catalogues of the Auctioneers, 1, Old Butter Market, Ipswich.

FREEHOLD. — SOUND INVESTMENT. — CAMDEN TOWN.—Well-built FREEHOLD FACTORY and FOUR FREEHOLD COTTAGES, rental £340, situate Ferdinand-place, Chalk Farm. Also Ground Rents, £18 per annum, well secured. Early reversion. WILL BE SOLD in ONE LOT, at THE MART, January 12, 1893 (unless previously disposed of) by Messrs. ROUCH and PARKHOUSE, Auctioneers, 7, Queen Victoria-street, E.C., and Crouch End, N. Low reserve. Write for particulars.

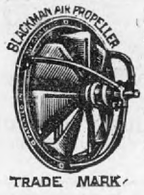
Extensive Laboratories, Dynamo Room, &c.

Students are regularly sent to the College by leading Engineers and Scientific Authorities, whose names are given in the Prospectus.



FOR VENTILATING AND COOLING ENGINE AND DYNAMO ROOMS,

20 HIGHEST AWARDS, including PARIS, 1889.

BLACKMAN VENTILATING CO. (Ltd.),

63, FORE STREET, LONDON, E.C.

SITUATIONS VACANT AND WANTED, &c.

REQUIRED, a REPRESENTATIVE, not under 30 years of age, by a large manufacturing firm, for the sale of Electric Light Accessories, Patent Lamp Holders and General Electric Light Fittings, to take London and most of principal towns in England. Must thoroughly understand this business, and be in touch with the principal engineers of note. None but thoroughly experienced will be entertained.—Apply by letter only, giving full experience, age, copy of credentials, and state salary required in confidence to SECRETARY, Evered and Co. (Limited), London.

WANTED, DRAUGHTSMAN, for leading London Electric Light Company, to get out general arrangements of central stations; must be quick. Salary £100 to £120.—Apply, stating age, to "G. B.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

AN ELECTRICAL ENGINEER who has had experience in installation work, desires SITUATION of similar capacity. Salary moderate. Good references.—Apply, "F. R.," 83, Downs Park-road, Clapton, N.E.

APPOINTMENT WANTED, as MANAGER or CHIEF ENGINEER of telegraph cable and insulated wire factory by an engineer who has had extensive experience in the design and manufacture of submarine, subterranean and aerial cables for telegraph, telephone and electric light purposes, and in the design and arrangement of special machinery for making such wires and cables. —Apply, 1119, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ELECTRICAL ENGINEER, just returned from abroad, seeks SITUATION. Has had theoretical training as well as 3 years' practical work, and 3 years' installing work. References and testimonials.—Apply by letter to "L. C. L.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ELECTRICIAN seeks EMPLOYMENT, 9 years' experience, thoroughly acquainted with accumulators, direct and alternating current, Arc or Incandescent; also repairs. Home, country, or abroad. Good references. Speaks French.—"M. G.," 45, Westmoreland-place, City-road, N.

ENGINEER seeks RE-ENGAGEMENT. Good experience in design, construction and running of all kinds of electrical machinery; central station and installation experience.—Address, Box 1117, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

TO COUNTY COUNCILS, CORPORATIONS and OTHERS.—ELECTRICAL ENGINEER desires ENGAGEMENT. Great experience in the laying and testing of Electric Light Mains, also Submarine Cables. For many years in the employ of one of the leading Telegraph Engineering and Electric Light Works. Highest references.—"ELECTRO," 44, Loftus-road, Shepherd's Bush.

WANTED, by young Electrician, APPOINTMENT as ENGINEER or ASSISTANT to Electrical Firm. Advertiser has had good commercial experience, and can supply excellent references.—1118, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

YOUNG MAN (19), after having completed 2 years at City and Guilds College, Finsbury, desires SITUATION in workshop, testing or drawing office.—Address "A. Z.," care of A. Hamlin, Esq., 9, Fleet-street, E.C.

MISCELLANEOUS ADVERTISEMENTS, &c., CONTINUED ON NEXT PAGE.

CHARLES ALCOCK, Secretary.
JOHN H. CROFT, Secretary in London.

THE
ELECTRIC CONSTRUCTION CORPORATION
(LIMITED).

ISSUE OF £100,000 SECOND MORTGAGE DEBENTURES
TO BEARER
(in accordance with report of Directors, dated December 8, 1892).

Bearing Interest at the rate of 6 per cent. per annum;

Redeemable by half-yearly drawings as under, and entitling the subscriber of each Debenture by way of bonus to an income bond of corresponding amount as undermentioned.

THE ELECTRIC AND GENERAL INVESTMENT COMPANY, Limited,
Of No. 1, Great Winchester-street, London,

are authorised by the Directors of the Electric Construction Corporation (Limited) to issue to the existing shareholders of the Corporation Second Mortgage Debentures of £10 each, in proportion to their respective holdings.

The Debentures are payable:—

£1	per Debenture	on 19th December, 1892.
3	„	on 16th January, 1893.
3	„	on 15th March, 1893.
3	„	on 15th May, 1893.
£10		

The first Payment of Interest will be made by Coupon attached to the Scrip Certificates, on the 1st July, 1893, and will be calculated at the rate of 6 per cent. per annum on the instalments, from the dates when they become due to the 30th June, 1893. Thereafter the interest will be payable on the 1st January and 1st July in each year by half-yearly Coupons attached to the Debentures.

The Debentures will rank next after the existing First Mortgage Debentures of £150,000 as a charge upon the whole undertaking and property of the Corporation present and future, and are secured by trust deed made between the Electric Construction Corporation (Limited), and the Electric and General Investment Company (Limited), the trustees.

The Debentures are redeemable at par by half-yearly drawings over a period of about 15 years, thus: A sum equal to £10,000—less 6 per cent. on the unredeemed and unissued (if any) Debentures of this series—to be paid over to the trustees annually, and to be applied by them in redeeming the Debentures of this series at par, in accordance with the provisions contained in the trust deed.

The Subscriber for each Debenture will receive by way of bonus an income bond for a like amount.

Such income bond will carry interest from the date of redemption of the corresponding Debenture as regards each year at a rate equal to the dividend declared on the ordinary shares for the preceding year, and such income bond will, in a winding-up, rank for payment next after the preference shares of the Corporation, and will be repayable in 50 years from date of issue or on the winding-up of the Corporation.

Drafts of the above-mentioned trust deed and of the forms of Debentures and income bond can be seen at the Offices of this Company, and at those of the Electric Construction Corporation (Limited), Worcester House, Walbrook, E.C.

Dated 9th December, 1892.

LARGE DIAMETER DYNAMOS.

Having Machinery suitable for dealing with Diameters up to 22ft., we shall be glad to undertake the production of Dynamos, &c., to above sizes.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 761.—Vol. XXX. FRIDAY, DECEMBER 16, 1892. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6.*

NOTES.

The public and formal amalgamation of the National and New Telephone Companies is a satisfactory proceeding, inasmuch as the separate existence friction has been done away with. As to any blessings which may flow to the public from this union of hearts—we shall believe them when we see them. At any rate, Government purchase has now been rendered a more simple, though probably a more costly process.

The County Court decision which is reported in our Legal Intelligence this week would be of the greatest importance were it not utterly absurd, and would, as the plaintiff urged, have a disastrous effect on electrical business, were it not a complete blunder. Messrs. Laurence and Scott carry on an electrical supply business at Ipswich, and one of their customers has demanded that the expense of lamp renewals should be thrown in for the asking. Without troubling themselves to appeal and without incurring any costs, Messrs. Laurence and Scott could probably set matters right by applying to the Board of Trade, who, whether they had any *locus standi* or not in the matter, would probably give the learned Judge a little elementary information which might be useful to him. It may be, but it does not appear from the evidence, that the plaintiffs have been foolish enough to make a contract for supply of *light*, but this seems hardly possible, although the Judge thought that the agreement, such as it was, gave the defendant to understand that the plaintiffs would "keep up the electric light."

At the Society of Arts on Wednesday last Prof. G. Forbes discoursed on Niagara, but was unable to give any information about the electrical part of the work, as twenty designs for the 5,000 horse-power generators are still puzzling the commission. We hear more about the new manufacturing city that is to be built, than about the cost of the power which is to be its *raison d'être;* nor are we any wiser as to the nature of the new industries which we have been assured will be created. Prof. Forbes puts forward, tentatively we presume, £5 as the value of one horse-power day and night, for a year, and deduces the very handsome annual income of £2,450,000. Bearing carefully in mind the difference of prices in this country and in America, we may compare this figure with the estimates recently given by Mr. Swinburne and by Messrs. Cross and Bevan, the constituent items of which were given in *The Electrician* of November 25th and December 9th respectively. Mr. Swinburne put down a kilowatt-hour at 0·241d., say, 0·18d. for a horse-power-hour; Messrs. Cross and Bevan give a horse-power-hour at 0·178d. The £5 of Prof. Forbes works out to 0·137d. per horse-power-hour. The Niagara power is only 24 per cent. less than Mr. Swinburne's estimate, say 30s. per horse-power-year. Out of this 30s. will have to be paid attendance, oil, and interest and depreciation on plant, all of which are included by Messrs. Cross and Bevan and by Mr. Swinburne, and out of the balance the new manufacturing city is to be built. We wish it all success. But, as we have already remarked, it is difficult to compare prices in the two countries.

Freshness and originality are not expected in Presidential Addresses, but in the address recently delivered before the Old Students' Association by Mr. Ll. B. Atkinson both these ingredients were present in an unusual degree. The study of human character and the motives which influence mankind is as old as civilisation, but to suggest that it should form part of a course of technics was both a refreshing deviation from the beaten track and the apotheosis of the technical education mania. We are happy in the conviction that a subject has at last been suggested that no formula can compass, and nothing short of actual practical experience of the world can teach. A youth certificated in electrical engineering, chemistry, astronomy, and—"human dynamics" would be too awful to contemplate.

Mr. Mordey observed during the discussion on Dr. Fleming's recent Paper that the members of the Institution of Electrical Engineers were apt to be a little squeamish when they came to discuss profits and commercial considerations. To speak of L was scientific, but to mention £ was bad form. Mr. Mordey was perfectly right in his estimate of the character of these discussions, and such squeamishness is only part of the idiosyncrasies of the Institution, and one which we had in view when, on a recent occasion, we held that it was a distinctly scientific body. At the meetings of the Institution of Civil Engineers no such delicacy is known. The saving of a few pence in boring a rifle barrel is put forward with pride as a crowning-point in the performance of an ingenious machine, while the losses by friction are not even alluded to. Nor, when the cost of docks runs into many thousands of pounds, is there any hesitation in giving the figures; they are, indeed, necessary for the proper appreciation of the subject. During the discussion on small arms, which has not yet been

Hosted by Google

closed, at the Institution of Civil Engineers, the price of different rifles was freely mentioned, but in a way that would simply shock dynamo-makers, for the trade or selling price was treated as of minor importance, depending simply on the relative smartness of buyer and seller. The prices quoted and compared were net cost prices.

THE attempt which has been made by M. PICOU to analyse the losses in transformer distribution would have been of greater value if he had taken some actual case or had worked out figures for an imaginary example. In his article, of which a translation will be found in another column, he gives a load curve, and adds to the useful load the losses which arise in the transformers and the mains. Amid all the theorising about transformers and the profusion of literature upon their losses, no one, so far as we are aware, has taken the trouble to calculate the C^2R losses in an ordinary alternate current supply station, or at all events to publish them. Dr. FLEMING has published hypothetical curves not unlike that of M. PICOU; but transformers as a system must be judged on actual examples from practice, and this becomes yet more imperative when one kind of transformer is to be compared with another.

WHILE some such diagram as that of M. PICOU may represent hypothetically an ordinary transformer service, it does not illustrate the losses with Hedgehogs, for the magnetising current with these transformers is, we understand, or ought to be, practically constant. The increase of power as the secondary becomes loaded is due mostly to change of phase, not, as in closed-circuit transformers, to increase of current. If we understand Mr. SWINBURNE rightly, the magnetising current gives rise to a nearly constant copper loss equal to about one-third that of the iron losses. This might be represented on the diagram by a line parallel to the iron losses. The load current, or that part of the primary current which rises with the load, entails a variable C^2R loss. But to draw these by eye on an imaginary curve is of no use at all. The objections to open-circuit transformers are chiefly directed to the heavy magnetising current, and before much weight can be attached to them some actual figures of the C^2R losses in mains must be produced. The losses in the secondary circuit, while interesting from a scientific point of view, have nothing to do with the present subject. The result is merely a drop, annoying perhaps to the consumer, but recognised and licensed by law, if not greater than 4 per cent., and it in no way affects the coal bill of the station.

THE condition of maximum efficiency given by M. PICOU only really applies when the C^2R losses include not only those occurring in the transformers, but also the average loss in the mains. Owing to the absence of data with reference to the latter losses, it is impossible to say how nearly this condition is fulfilled in modern transformers. In nearly all those tested by Dr. FLEMING the copper losses at full load are less than the core losses, so that the efficiency increases continuously up to full load. The Ferranti and Thomson-Houston transformers practically attain their maximum efficiency at about three-quarter load, and this shows that the copper losses in the transformers are, at full load, greater than those occurring in the iron. For the average load, however, the copper losses are less than those in the core, and when the losses in the mains are added, it is probable that M. PICOU's condition of maximum efficiency represents very nearly the condition of actual practice with closed circuit transformers. The instrumental details of measuring transformer losses as carefully investigated by Dr. FLEMING, and the estimation of these losses per cubic centimetre of iron and copper by Prof. EWING, are valuable in their proper place; but the real question for the engineer, as was pointed out by Mr. CROMPTON, who, by the way, meets with small thanks for his trouble, is "the enormous difficulty of ascertaining where the losses really do lie in alternating systems of distribution."

WE print this week an interesting Paper by Prof. ROWLAND on the effect of harmonics in alternating current circuits. We are, however, inclined to think that the importance of these harmonics is much over-estimated. They may sometimes represent 20 per cent. of the current, but, if so, the power they denote is only this percentage of the *losses* occurring in the mains. In alternating current circuits the loss in the primary mains represents a small fraction only of the power transmitted, and any harmonics occurring in the secondary circuits are useful, since secondary circuits are only used for lighting purposes. These harmonics are mainly caused by the presence of hysteresis in the cores of the transformers or motors worked by the current, and they represent the extra excitation necessary to make the magnetism of the iron follow strictly the variations of the potential of the mains. The power which is represented by the product of the voltage of the mains, and the effective value of these harmonics, is that which is absorbed in hysteresis, and this cannot be diminished except by the substitution of better iron. The practical conclusion to which Prof. ROWLAND comes, that the cores of transformers and the armatures of alternators should be worked at a much lower induction than 12,000 lines, is an old one now, and one which has been acted upon for some years. Indeed, there are few transformers made at the present time worked with a maximum induction of as much as 5,000 lines.

Hampstead Vestry.—The Electric Lighting Committee of this Vestry has recommended the Vestry to under take the electric lighting of the parish, under their Provisiona Order, and to borrow £25,000 for the necessary plant.

Bristol.—It has been decided to have handsome gas standards placed upon St. Augustine's Bridge, notwithstanding that the electric light mains are to be carried over the structure. The standards will, however, be suitable for electricity as well as gas.

Nottingham.—The Town Council, after a long and interesting discussion, decided on Monday last to adopt the scheme for lighting part of the town by electricity, which has been previously referred to in these columns. (See *The Electrician*, December 9th, p. 147.)

Yarmouth.—At the last meeting of the Town Council it was decided to apply to the Local Government Board for sanction to borrow £15,000 for the purposes of electric lighting. This sum will allow of from 50 to 100 arc lights for public street lighting, in addition to 14,500 private lights.

Southport.—On Thursday last Col. Hastead, R.E., Local Government Board Inspector, held an inquiry at the Town Hall respecting an application of the Corporation to borrow £28,000 for works of electric lighting. After evidence had been given the inquiry concluded, there being no opposition.

Derry.—At a recent meeting of Derry ratepayers protests were made against the efforts of the Corporation to be entrusted with the power to borrow £40,000 for the electric lighting of the city. Eventually it was resolved to employ legal and expert assistance, and to appear before the Local Government Board to oppose the loan.

The Diffusion of Light.—A Paper of unusual interest was presented to the Physical Society by Dr. Sumpner on Friday last. Only a small portion was read, and some discussion followed. The practical bearings of this subject are of so great importance in electric lighting that we withhold the usual abstract until we are able to publish the Paper in full.

Taunton.—The statutory inquiry as to the proposed purchase of the electric light works by the Town Council was, as we announced last week, fixed to take place on Tuesday; but it having been represented to the Board of Trade that that date would be inconvenient, it was decided to postpone the inquiry until to-day (Friday), when Sir Thomas Blomefield and Major Cardew will open the proceedings at 10 a.m.

Royal Institution.—Among the lectures arranged for before Easter are the following :—Sir Robert Ball, six lectures (adapted to a juvenile auditory) on Astronomy; Prof. Victor Horsley, ten lectures on The Brain; Lord Rayleigh, six lectures on Sound and Vibrations. The Friday evening meetings will begin on January 20th, when a discourse will be given by Prof. Dewar on Liquid Atmospheric Air. Succeeding discourses will probably be given by Mr. Alexander Siemens, Mr. Edward Hopkinson, Lord Rayleigh, and others.

Wolverhampton.—The Electric Lighting Committee of the Town Council have decided to recommend the adoption of the tender of the Electric Construction Corporation for £28,772 for laying down an alternate-current system. It is proposed to appoint Mr. W. H. Preece engineer; also an architect and a deputy-engineer or clerk of the works, at a salary not exceeding £250 per annum, subject to the engagement being determined by one month's notice on either side. The details of the tenders sent in will be found in our Trade Notes column.

Windsor.—On Friday last a special meeting of the Town Council was held to consider the breaking up of the streets by the Windsor and Eton Electric Light Company. After much discussion it was moved and carried by 12 votes to 9 that the Town Clerk should be instructed to take action against the Electric Light Company for breaking up the streets without legal authority, under section 149 of the Public Health Act. An addendum was proposed and carried by 10 votes to 8 to the effect that counsel should be instructed to ask for only a moderate penalty.

"Irish" Electric Railway.—Mr. W. E. Irish, of Cleveland, Ohio, has sent us a description of what he calls "a closed electric conduit system." The conduit has, however, an open slot, through which a hanger passes and carries a trolley with two wheels. These press against two conductors hung to the top of the conduit. Each conductor is enclosed in an indiarubber tube, on the outside of which contact pieces are fastened. As the trolley passes underneath the conductors, the elastic tube is pressed upwards by the trolley wheels, and contact is made with the conductor.

Cable Interruptions and Repairs :

THE FOLLOWING CABLES ARE ACTUALLY INTERRUPTED :

	Date of Interruption.
Bolama-Bissao (communication with)	September 9, 1892
Cayenne-Vizeu	September 24, 1892
St. Thomé-Loanda*	November 24, 1892
Penang-Medan.....	December 1, 1892

* Communication with South Africa is still maintained by the East Coast route.

Bolton.—The Corporation are seeking powers to introduce electricity into the town, both for lighting and power purposes. The Corporation are the owners of an extensive gas undertaking, and it is proposed, for some time at least, to confine electricity to manufacturing establishments, tradesmen's premises, and other similar consumers. The Corporation are seeking powers to work the tramways themselves, and in the event of their doing so, electricity is being advocated in various quarters as the motive power. The motion for the Bill embodying these powers recently came before the Town Council and was carried by 21 to 11. A two-thirds majority not having been obtained, the matter will have to come before another meeting.

Obituary.—The death is announced of Mr. John R. H. Williamson at Allandale, near Sydney, on the 8th inst., at the early age of 33 years. Mr. Williamson became connected with electric lighting, and was quickly appointed Managing Director of the Manchester Edison-Swan Electric Light Company, and under his able management that Company attained a position of considerable success. Unfortunately his health broke down, and he left England three years ago for New South Wales, where he again embarked in electric lighting, undertaking several important contracts for the lighting of Sydney. Increasing ill-health, however, again necessitated his entire relinquishment of business.

The Funeral of Dr. Werner Siemens.—The German Emperor was represented at the funeral of Dr. Werner von Siemens on Sunday last by Prince Leopold. The Empress Frederick was represented by Count Seckendorff, and the German Empire by Chancellor Caprivi. The London, Vienna, and St. Petersburg Siemens factories each sent 10 officials and 10 workmen. Among the various notabilities present were Dr. von Bötticher, Minister of the Interior; Baron von Berlepsch, Minister of Commerce; and Dr. von Schelling, Minister of Justice; while representatives of the City of Berlin, and of the town of Charlottenburg, and numerous members of artistic and scientific societies, likewise attended. Mr. Edison sent a wreath.

Nîmes.—At Nîmes it appears that the electric light cables are leaking. *Sciences et Commerce* says :—"A certain number of house owners are complaining of the bad insulation of the cables of the National Electric Company. On some days, by merely touching the awning supports of many of the houses on the Rue de la Banque, one may treat oneself to a little electro-therapeutic séance, and at the same time save the penny which this amusement usually costs at the automatic machines. The Company, apprised of this state of things, which might have serious consequences one of these fine days, will surely apply itself to a better surveillance of its cables, and to the improvement of its insulators."

City and Guilds of London Institute.—The presentation of prizes and certificates in connection with the City and Guilds of London Institute for the Advancement of Technical Education took place on Monday evening last at Merchant Taylors' Hall, the Lord Mayor presiding. Those present included Dr. Anderson, F.R.S., Sir Frederick Bramwell, Sir Frederick Abel, Sir Philip Magnus, and others. The Lord Mayor opened the proceedings, and heartily welcomed the students of the Institute to the City. Dr. William Anderson presented the prizes and afterwards addressed the students, urging them not to rely too much on theoretical knowledge, but to remember that practical experience, though obtained very slowly and often at great cost, was essential to success in their professions.

Plymouth.—With reference to the tramways question the Works Committee reported at the last meeting of the Town Council that there was no intention of introducing into Plymouth the overhead trolley system of electric traction, but that they thought it desirable to apply for similar powers of working the new lines by electricity as the Corporation possessed with reference to the existing lines, so that the Corporation might be in a position to avail itself of electricity as a motive power, should experience hereafter demonstrate that it could be economically used without detriment to the public interest. The Committee also reported that the Board of Trade had sanctioned the borrowing of £8,500 for the purchase from the Tramway Company of the depôts, rolling stock, plant, and horses.

Proposed Clapham Junction and Paddington Railway.—The proposed railway from Paddington to South Kensington,

Hosted by Google

which met with such strenuous and effective opposition last year, both from scientific men whose laboratories would be disturbed, and from many residents in the neighbourhood, has been put forward again, as we recently noticed, with an extension to Clapham Junction. This, no doubt, gives a little more reason for the construction of this line, but it seems to be admitted that it is to act chiefly as a feeder to the various institutions, museums, &c., at South Kensington, and especially to the Albert Hall. We understand that there will be a station actually within the Albert Hall itself. It is assumed that by having a deep tunnel, some 70ft. below the surface, the scientific laboratories will not be affected.

Technical Education.—One of the many rocks ahead of the technical education craze seems to be foreshadowed in a dispute which has arisen in the Dundee Technical Institute. The Institute has a plumbing class which is attended, amongst others, by two tinsmiths and a blacksmith. The presence of men not connected with the trade was objected to by the regular plumbers, and they requested the Committee of the Institute to restrict the attendance at the class to journeymen and apprentice plumbers. The Committee have not as yet agreed to concede the request, and meanwhile the plumbers threaten to boycott the class. The National Registration of Plumbers' District Council have proposed to the Committee that the class should either be conducted as an exclusive trade class, or that the teaching should be confined to the principles of the plumbing craft as defined in the Technical Instruction Act of 1887.

The Blackening of Glow Lamp Bulbs.—Writing to *L'Electricien*, with reference to the statement of Prof. Thomas that the bulbs of glow lamps exhausted by mechanical pumps blackened less than those exhausted by mercury pumps (see *The Electrician*, Vol. XXIX., p. 331), M. Bainville, works manager to the "La Française" Glow Lamp Company, says that in his opinion the mercurial vapours which may possibly be present within a lamp bulb are quite insufficient to explain the phenomenon. M. Bainville suggests that occluded oxygen is the true cause, the oxygen being present either in the residual air, in the vapour of water which adheres so strongly to the glass, or in the filament itself. This occluded oxygen in the presence of the incandescent carbon forms carbonic oxide, which, coming into contact with the relatively cold wall of the bulb, splits up, depositing the carbon and leaving the oxygen free for fresh attacks.

An Iron Ship Struck by Lightning.—Captain Woodcock, of s.s. "Capella, has given the following account of his vessel being struck by lightning on May 16th, in latitude 8 12 N., longitude 70 50 E. The "Capella" is a steel steamer, fitted with two masts, the lower portion being of iron and the topmasts of wood. The morning was squally and thundery, and about half-past seven there was a very vivid flash of lightning, accompanied by a violent explosion by the rail near the starboard fore rigging, which seemed as if something had exploded. The foretop-mast was splintered near the spirs, and some service torn off the top-gallant backstay. The shock also affected the compasses. The shock had changed the magnetism of the ship so much that it reversed the cards. Since the occurrence the compasses have never regained their original errors, and the magnets have had to be moved, and some reversed, to reduce the errors.

Telegraph Construction on the Kohat Frontier. — An excellent piece of construction, says the *Indian Engineer*, was carried out last month on the Kohat frontier by Mr. Oldbury Burne, assistant-superintendent of telegraphs, assisted by Lieutenant Greer, R.E. Orders were issued on September 7th to extend the line from Hangu to Thall, in connection with the occupation of the Kurram Valley. The stores were procured from Rawalpindi, and had to be carried 80 miles by rail to Kushalgarh, and 45 miles by road to Hangu. Notwithstanding that the working party were attacked by cholera, and that the distribution of posts and wire had to be made by coolie and donkey transport, the 41 miles of line were completed by the 1st inst., on which day an office was opened at Thall. The experience gained here and on the Haripur-Darband route has conclusively shown that the field telegraph equipment now in use is thoroughly well adapted for the purpose for which it was designed.

The Indo-European Telegraph.—The resolution of the Government of India on the working of the Indo-European Telegraph Department last year notes the increase on the capital account of eighty thousand odd rupees, mainly due to a payment on account of the extension of the Persian concession. The traffic earnings were higher by two lacs and eighteen thousand than in the previous year owing to a larger number of messages having been carried. The year's transactions show a net profit of one lac and sixty thousand compared with a loss during the previous year of eight thousand rupees. The net profit is equivalent to a return of ¼ per cent. on the capital outlay. The average length of the messages is increased owing to the reduction in the Australian tariff. There were fewer complaints of error and delay, and practically no interruption; but the number of acts of wilful damage on the Persian section are much more numerous, the increase being attributed to the year having been one of disturbance and excitement in Persia. But compensation was received as usual, and the good relations existing between the Persian authorities and the *employés* of the department were in no degree affected.

Cathedral Lighting.—The *Neue Freie Presse* of Vienna discusses the advantages and disadvantages which attend the electric lighting of St. Stephen's Cathedral, which has lately been introduced. From a practical point of view the lighting is all that could be hoped for. The twelve large hanging lamps, each 1,000 candle-power, suffice to spread a brilliant light into every part of the great church. The light also brings out the details of decoration and of the architecture, as it is never possible to see it under other conditions, because no other light is so equally distributed from the ceiling to the ground. But this may not be altogether an advantage, as an architect naturally arranges his parts with distinct reference to the distribution of light, as it is permitted to enter by the windows or dome. And as regards the building as a whole, its appearance is certainly not improved by the absence of due shade. What is here stated must apply more or less to all large Gothic buildings. The fault lies not in the strength of the light, but in its position. It can never have the same effect as that got by the sun's rays entering through side windows, and it was with reference to such lights that Gothic cathedrals were built.

Electric Lighting Legislation in Victoria.—At the monthly meeting of the Victorian Institute of Engineers, held on October 5th, the report of the Committee appointed to inquire into the Electric Lighting Bill was read by Prof. Kernot. The Committee stated that they were in favour of electrical legislation, but the Bill appeared to them defective in the following respects:—It failed to specify the ultimate authority by whom disputed points were to be settled. The fixing of a maximum price of 9d. per Board of Trade Unit was undesirable. If any limit had to be fixed to the price of electricity, it should be high enough to allow for the increased cost of production in small towns and places where motive power was specially expensive. The Municipal Councils were given dangerous power in imposing special by-laws. Too much power was given to the Postmaster-General. The Committee suggested that a Central Board, consisting of representatives of the Postal and Railway Departments, City and Municipal Councils, Metropolitan Board of Works, and Electric Supply Companies should be appointed, with power to frame regulations, settle disputed points, inspect and, if necessary, condemn imperfect and unreliable appliances, adjust disputed charges, determine the hours of supply, the location of conductors, character of insulation and supports, and perform any other duties that might be necessary to ensure a reliable supply of electricity to the public and a secure tenure to the undertakers, and at the same time protect the interests of the Postal and Railway Departments and other interested bodies; and that all municipal and departmental by-laws relating to electric supply should be subject to the approval of this Board. If such a Board were organised, and the other modifications proposed in the previous part of the report attended to, the Committee believed that the proposed legislation would be beneficial and satisfactory to all concerned.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 87.)

23. The Old "Monarch" and Her Modern Namesake.—The earliest events in the history of cable laying and repairing will never cease to retain their interest. From the year 1850, when the first telegraphic submarine cable of any practical utility was laid, namely, that between Dover and Cape Grisnez in France, up to the first Atlantic Expedition of 1857, a vast amount of pioneer work in the laying and repairing of what would now be called shallow water cables was carried out. Cables were laid between Holyhead and Ireland, Scotland and Ireland, England and Belgium, and England and Holland, and during this period great progress was made in the design of machinery used in laying and repairing cables, the fitting out of ships as cable ships, their handling under heavy weather when working cable, in the manufacture of cable, and in the development of a system of electrical testing. The names of Messrs. Willoughby Smith and Latimer Clark, electricians; Messrs. Wollaston, Crampton, R. S. Newall, Reid, Edwin Clark, and F. C. Webb, engineers, and Messrs. J. and J. W. Brett, are well known as those to whose skill and indomitable perseverance was due the grand pioneering achievements of that time. It was then the custom to petition the Admiralty for the assistance of one of Her Majesty's ships during the laying of a new cable, a request freely accorded, and the names of Captain E. Burstall, R.N., and Captain J. Washington, R.N., fill an important *rôle* in the history of these early enterprises.

A peculiar intrinsic interest, attaches to the cables, past and present, connecting Great Britain and Ireland and the British Isles with the Continent; not only because their history is of such significance, in view of the incipient stages of the enterprise, but the whole system of their maintenance in the present day, coming under the control, as it now does, of the Government, must be of interest to most Englishmen, whilst the manner of coping with the special difficulties attending repairs near our coasts in shallow water of great tidal force is of no small technical interest. Of the cables touching our shores, with the exception of these to Norway, Denmark, Spain, Portugal, America, and their connections which belong to private companies, the whole network of cables between Great Britain, Ireland and adjacent islands, together with those across to France, Belgium, Germany and Holland, are kept in repair by our own Government telegraph ships, H.M.S. "Monarch" and H.M.S. "The Lady Carmichael." The two cables to the latter country belong to our own Government, while those to the three former countries are jointly owned by our own and their respective Government subject to a joint purse arrangement. The behaviour of the "Monarch" under peculiar difficulties while laying the Channel telephone cable through which London is now in direct speaking communication with Paris, attracted considerable public attention in the early part of last year, and this vessel (illustrated in Fig. 85), to which reference will be made presently, is in build and fittings admirably designed for her special work. First, however, the writer wishes to review some of the work done by the pioneer vessel of that name, justly called the first cable ship. This does not mean she was the first vessel from which a submarine cable was laid, for preceding her the steam tug "Goliath" laid the unsheathed cable to France in 1850, H.M.S. "Blazer" that in '51 over the same route (this cable being still in good working order), the steamer "Britannia" the first Irish cable from Holyhead in '52, and the second from Scotland, and the steamer "William Hutt," the first cable to Belgium in '53.

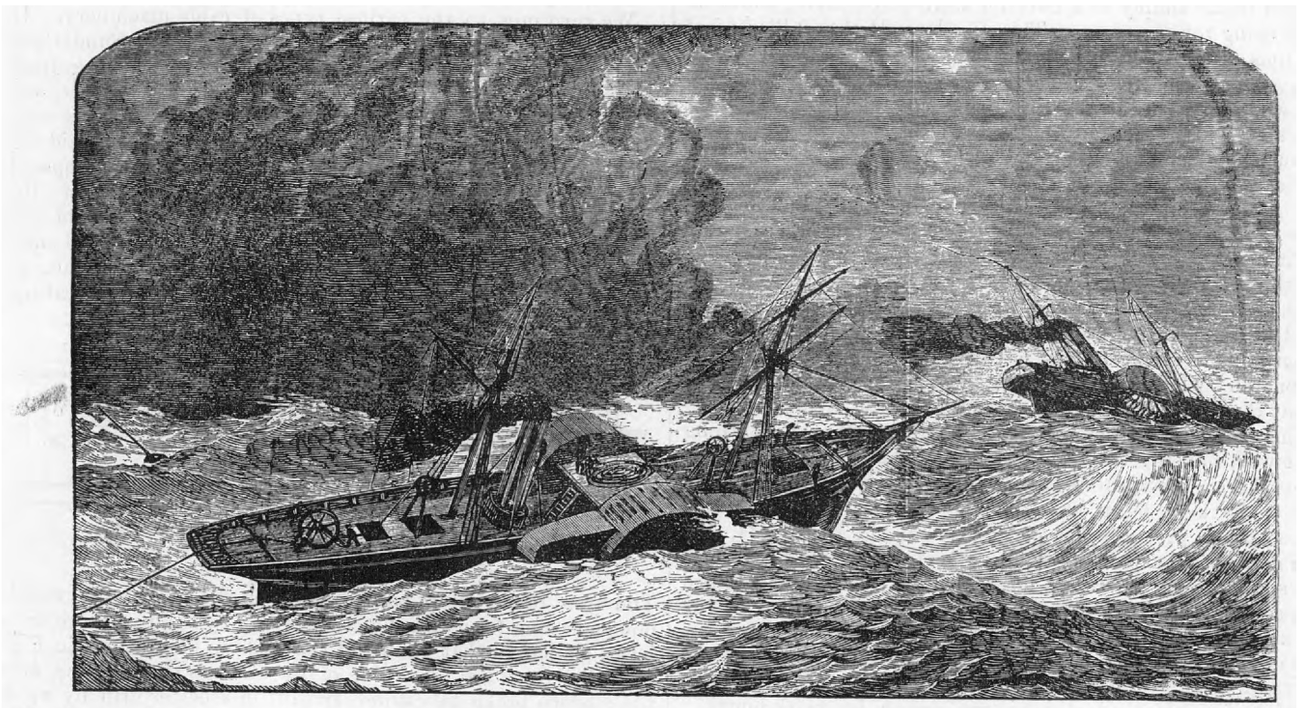

FIG. 81.—The old "Monarch" laying Cable from England to Holland, 1853. H.M.S. "Adder" in company (This illustration is reproduced from the *Illustrated London News*, of June 18, 1853, by kind permission of the Editor.)

But the "Monarch" was the first ship that grappled for a lost cable and successfully carried out a repair, and on her was fitted the first picking-up machine ever made. Besides this, her paying-out brake was the embryo of that in use at the present day, and the system of buoys, mushrooms, sheaves and steam gear was originated in her.

The illustration of this vessel (Fig. 81) (reproduced from the *Illustrated London News* of June 18, '53, by the courtesy of the editor) is from a sketch by Mr. F. C. Webb, and represents her laying one of the Hague cables from Orfordness in that year, this being her first operation. She was a wooden steamship of 500 tons, with paddle wheels, and was already 23 years old when bought by the International Telegraph Company for laying the above cables. The expedition is of interest, as showing the practice in those days. The cable (136 miles) was distributed in five coils, two in the main and three in the fore hold, coiled alternately in order to keep the ship trimmed during paying-out. Ships are now built with water ballast tanks which can be pumped up or discharged, as trimming is necessary, while loading or paying-out. The coils

* All rights reserved.

Hosted by Google

were oblong, which economised room in the holds, but were not so simple to uncoil as circular ones. In paying-out from these coils, in order to allow sufficient vertical height for the turn put in in coiling to untwist itself, the cable was led over an iron saddle or sheave erected on shear legs on deck 10ft. high immediately over the hatch. These may be seen in the illustration, one over each hold. To prevent cable running out too free the turns of the coils were stoppered down in places to the underneath turns by rope yarns. While paying-out, the stoppers were cut adrift and cable cleared away by twelve men stationed in the hold.

A perusal of the works on this and earlier expeditions from which these particulars have been gathered, viz., the Paper read on February 23, 1858, before the Institution of Civil Engineers, "On the Practical Operations Connected with Paying-out and Repairing Submarine Telegraph Cables," by Mr. F. C. Webb, and "Old Cable Stories Retold," a series of interesting articles in *The Electrician*, Vol. XIII., by the same author, conclusively shows that the greatest difficulty experienced was in steering. Towing was tried and given up, although this was a great assistance until matters were better understood. For instance, when laying the first sheathed cable (Dover to Calais, 1851), it was not deemed prudent to trust one vessel to carry it, lay it, and keep her course across channel. A vessel was, therefore, secured to act simply as a hulk for storing and laying the cable while being towed across. This vessel was H.M.S. "Blazer," of 500 tons, from which the engines and boilers were previously removed. When well on her way across, the hawser parted, and while renewing it, the ship drifted in the tideway, paying out cable nearly at right angles to the true course. Another similar experience was with the second Irish cable (from Port Patrick), which was laid without the aid of a tug. With the strong tide which runs through the North Channel, on her beam, and a light breeze aiding it, it was found only just possible to keep the "Britannia" on her course, and when about two-thirds across, the breeze increased in force and overpowered the helm, swinging her round stern to sea and tide. The cable was thereupon cut and let go.

Acting on this experience, a tug was procured to tow the "Monarch" while laying the Hague cables, and she was towed out at the start, but finding her answer the helm well and relying on her engines, the tug was cast off. Everything went well, but Mr. Webb relates that in the beam sea depicted in his sketch, when cable was all out of the forehold, the helm had to be kept hard over. During this north-easter which made things pretty lively for 22 hours out of the 34, Mr. Latimer Clark was below keeping up continuous electrical tests and speaking the shore at intervals, Mr. Spencer was lashed to his post at the brake, which in those days was worked by the pressure of a hand lever, while Mr. Webb, who assisted Mr. Edwin Clark, the Engineer to the Company, attended to the steering. The "Monarch" was pilcted by H.M.S. "Adder," which had previously laid down the course by mark-buoys, 8 miles apart. By steering for the buoys as indicated by the pilot vessel, the cable was laid with only 4 per cent. slack, a remarkably straight course considering the weather and tide. Mr. Webb about this time rendered great service in devising a table in which by inspection could be seen how a ship's head should bear, and what her speed should be for a given speed of paying out when set, and rate of tide were known, in order to lay cable in a straight line.

It is now known that a ship is much better under control in strong tideways by paying out cable from the bows. With a sea or tide running, say, at right angles to the proposed route, the cable is payed out from the bows on the weather side and the ship's head kept in a direction between those of the route and tide, the exact angle depending on the velocity of the latter. By this means cable falls clear of the ship, and with her head to the weather and stern free she is easily steered. When paying out from stern, the weight of cable hanging is almost equal to anchoring the ship, with the result that she is easily swung round in a beam tide. These remarks apply only to shallow water work in strong tides, such as prevail round our coast. Moreover, the heavy armouring necessary to resist wearing effect of tide wash increases weight hanging to ship and brake power required. In deep sea work these considerations do not apply. Cables are light, brake power small, and no tides to cross, and it is found that for lengths above ten miles paying out from stern is preferable.

On this point Sir Charles Tilston Bright, in his Paper before the Institute of Civil Engineers in November, 1865, on "The Telegraph to India, and its Extension to Australia and China," describes how he laid the Persian Gulf cables from sailing vessels towed by steam vessels. Five sailing ships had between them brought 1,234 miles of cable from England to the Gulf, each vessel being fitted with three tanks, paying-out drum, brake and stern sheave; and on arriving on the spot were towed during the laying by Government steamers. Sir Charles Bright said in this Paper that "he considered that in some cases, such as the work now described, where the cable was to be laid in a sea rarely subject to disturbance during the season for submergence, and where the depth of water was not great, sailing ships, towed by steam vessels, might be employed with safety, and it would be found that the economy in so doing, when the cable had to be conveyed a great distance to its destination, was very considerable. In this instance no difficulty of any kind was experienced. The steamer towed the cable ship with two hawsers, and the ships were in constant communication by a complete system of signalling."

We turn now to the earliest types of cable machinery. In the earliest appliances Mr. R. S. Newall, of the Sunderland firm of that name, took a prominent part in breaking fresh ground. His experience in the manufacture of wire rope, and the use of winding engines in collieries in the North, was used to great advantage. His firm having sheathed and laid the three cables to Ireland and that to Belgium, he was prepared with a very practical form of paying-out brake for the "Monarch" on the Hague expedition. This was a drum and brake in one, mounted between bearings on a horizontal shaft exactly similar to the drum and brake in the picking-up machine in Fig. 84, though, of course, without the spur gearing.

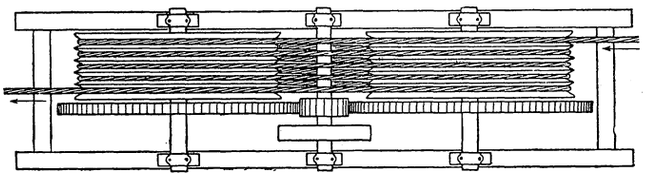

FIG. 82.—Plan of earliest Picking-up Machine (1853).

The iron brake strap bore directly on the face of the wheel, one end being fixed and the other set up by hand pressure on a lever, similar to that shown in the picking-up machine in Fig. 83. This was the best thing of its kind up to that time, and the modern brake only differs from it in a better grip by wood blocks and in means for mechanically setting it up by weights or a right and left-handed screw, making an easier adjustment by hand in place of entire manual effort. The brakesman of to-day has an easy job compared with his predecessor of 40 years ago, as the brake is now set to about the strain necessary for a given percentage of slack, and he has only to ease the wheel one way or the other as the stern rises or sinks in pitching.

The first picking-up machine (illustrated in plan in Fig. 82, from a sketch kindly supplied to the writer by Mr. F. C. Webb) was also the work of Mr. Newall, and fitted by him to the "Monarch" for recovering the cable, which, as related above, he was forced to cut and abandon when two-thirds of the distance from Scotland to Ireland had been successfully laid. The successful grappling for, and picking-up of these 16 miles was the first instance of the kind. It is evident that Mr. Newall anticipated heavy work, as he placed two drums tandem, each having five grooves in which the cable was wound backwards and forwards. From the bows it was led over the top of the after drum, taking half a turn, then on to forward drum, leaving this at the top and going round aft drum again, and so on five times. The machine was worked by a small steam engine driving the pulley by a belt. Although never used for the same purpose again, it was not a bad

Hosted by Google

design where a large bearing surface was required, as proved by Sir Charles Bright using tandem-grooved wheels for paying-out drums in the "Agamemnon" on the second Atlantic.

After this operation the "Monarch" was again on repairs under Messrs. Edwin Clark and F. C. Webb, who jointly devised the first single-drum picking-up machine (Figs. 83 and 84). Spur gearing was arranged, as there shown, with square shafts at A and B for winch handles. These were prolonged both ends to bearings on gunwale, so that 20 men could be put on each side to turn the handles. About 25 turns of the first shaft A made one revolution of the drum. The ratchet-wheel on the drum shaft was to prevent any cable running back during pitching. Men were also put on to draw cable taut off drum, as there was then no hauling-off gear. Over the bows was fitted a 3-foot sheave between two timber baulks 12in. square. By degrees improvements were made. Manual work was superceded by steam, a 4½ H.P. engine being fitted to drive the pulley on shaft A, and then the ratchet was discarded. This design of gear made a very distinct advance, and was the germ of that now generally in use; in fact, with the addition of the hauling-off gear in '57, Mr. Webb's overhanging drum in '63, and improvements in the brake, we arrive at the principle of most modern machines.

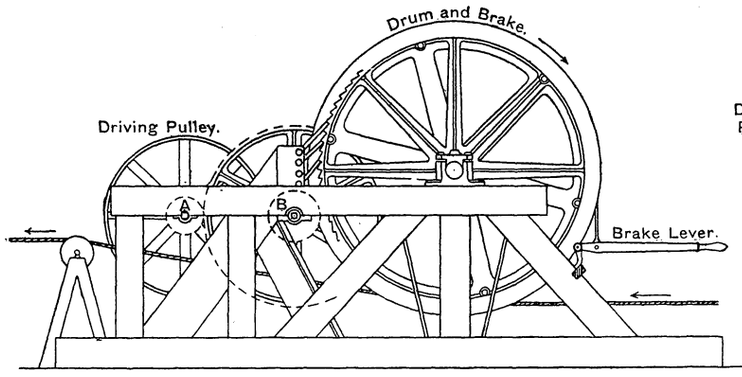

FIG. 83.—Earliest Single Drum Picking-up Gear. 1854.

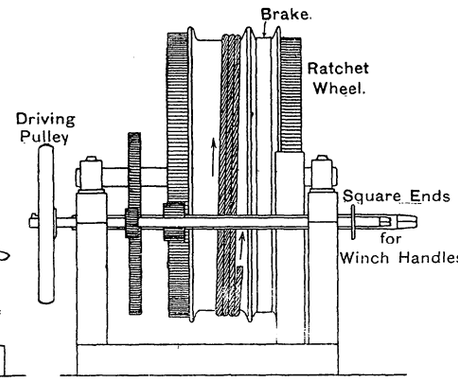

FIG. 84.—End View of Gear.

The steamer specially built in 1883 to maintain Her Majesty's telegraph cables was fittingly christened the "Monarch," keeping up the name of the now derelict steamboat, whose remarkable pioneering achievements have been briefly sketched. The illustration of this fine screw-steamer (Fig. 85) is from a photograph by Mr. W. R. Culley, electrician on board the "Lady Carmichael," to whose courtesy, and that of Mr. W. H. Preece, F.R.S., Engineer-in-Chief and Electrician to the Post Office, the writer is indebted for the accompanying details of these two vessels. The "Monarch" was built at Port Glasgow by Messrs. D. J. Dunlop and Co., her measurements being 240ft., by 33ft. beam, by 20ft. deep, indicated horse-power 1,200, and displacement at 15ft. mean draft, 2,073 tons. In view of the large compound-cored cables, weighing over 30 tons to the mile, which she has to deal with, her picking-up gear was made specially strong. It is composed of two sets of double-purchase gear, to each of which is a drum and brake, so that picking-up and paying out can be carried on at the same time. The gear is driven by a double-cylinder steam-engine, with usual reversing links and levers, and is capable of bearing a strain of 50 tons at the bows. The bow balks with two sheaves are built in to the head of the vessel, and the bows tapered gradually, so as to give a considerable overhang of the sheaves over the cutwater. This build is not apparent in the illustration, but as viewed broadside the sheaves jut out a considerable distance, and fit snugly into the taper of the bows. The primary object is to facilitate cable work from the bows, chiefly in paying out, so that the cable shall fall clear of the ship even when there is a very small angle between ship's head and route of cable. More deck space forward, where it is wanted, is also secured by this

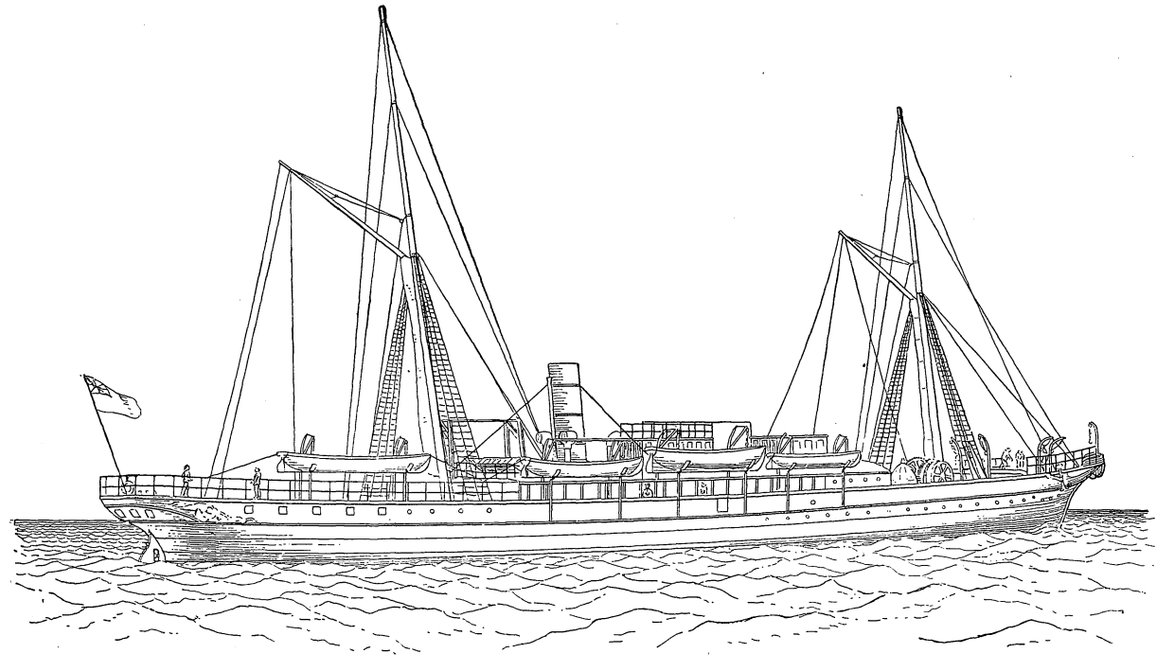

FIG. 85.—H.M. Telegraph Ship "Monarch."

Hosted by Google

construction. The design was first applied to this ship, and its utility demonstrated, and several ships since built have adopted the principle. Evidence that repairing and laying in shallow waters of strong tidal force is exclusively bow work is manifest in walking along the after deck of this vessel. The old holding-down bolt holes for securing brackets of cable leads sheave and brake in paying out aft are seen plugged up. The gear can be rigged in a very short time if necessary, but is practically shelved. The ingenious adjustable friction table devised by Sir Charles Bright for the cable ship "Dacia" is fitted on the "Monarch" in a suitable position for cable to pass through on its way to the paying-out gear forward. It is hoped to illustrate this later.

The "Monarch" carries two life-boats and one steam launch specially for landing and repairing shore ends. A raft is made of the boats lashed together with joists and planks across, forming a sound floor on which ten tons of cable can be coiled. A curious form of dynamometer is fitted forward in which the sheave is normally horizontal, mounted on a vertical shaft about 18in. high. As the strain comes on the wheel, the shaft is pushed out of the vertical, and by means of an arm moves a piston in a cylinder containing mercury. The mercury then escapes from a small hole in the cylinder, and rises in a tube on which the strains are graduated. As a matter of fact, the apparatus is not used, but this is mostly owing to the fact that dynamometers are not needed in shallow water work.

(To be continued.)

A BALLISTIC GALVANOMETER.

The remarkable outburst of scientific research in the United States during the last year or two has resulted not only in several valuable Papers which have from time to time appeared in these columns, but has created a demand for high-class instruments. Until recently these have been supplied largely from this country, not because our workmanship is better than that of the best American workshops, but because the apparatus was to be bought ready-made. Among the

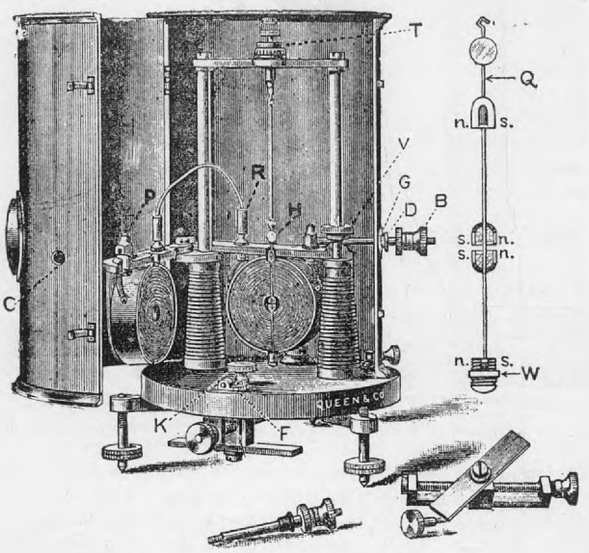

FIG. 1.—New Standard Ballistic Galvanometer.

leading Transatlantic firms Messrs. Queen and Co. are well known for careful design and accurate finish, and the latest of their productions is described in the *Electrical Engineer* of New York as "a new standard ballistic galvanometer with variable sensibility and without 'drift.'" When a measuring instrument is dignified by the title Standard, it commands special attention, though the precise difference between this and any other class of instrument is difficult to define. In all probability American instruments of precision, to use a French expression for which we have no equivalent, will assume a character of their own just as their machinery has done. This will be due partly to the different nature of the conditions of use and user, as well as to those causeless *nuances* which enable a sailor to tell the nationality of a vessel by the cut of her rig.

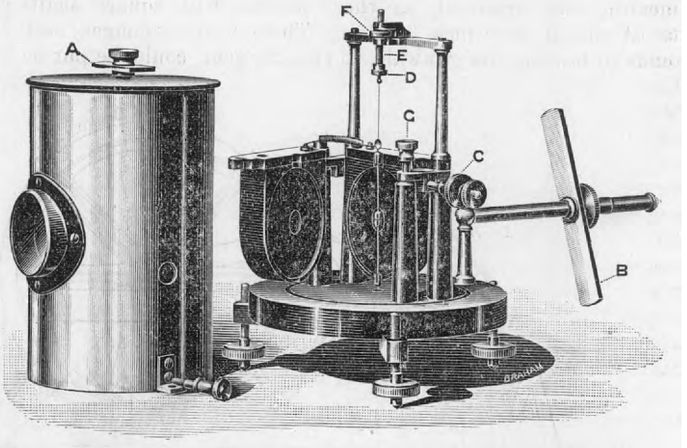

FIG. 2.—Messrs. Nalder Bros.' Ballistic Galvanometer (1891).

The galvanometer illustrated in Fig. 1 has been designed by Mr. E. F. Northrup, and it is no disparagement to say that it closely resembles in many respects an instrument made by Messrs. Nalder Bros., and described in *The Electrician*, Vol. XXVI., p. 610. We reproduce the illustration of the English galvanometer for comparison, not necessarily invidious, but none the less instructive.

FIG. 3. Nalder Ballistic Galvanometer. Details of Needle System.

The method of hingeing the coils which has been adopted by Messrs. Nalder Bros., and the mounting of the suspension bridge on two pillars, were, no doubt, worthy of exact repetition, but the corrugation of the ebonite posts is of doubtful advantage. If corrugations are used at all they should be deep and with well-rounded corners, but Messrs. Queen and Co. cut 60deg. grooves, which only double the effective surface, and their shape must accentuate the difficulties in cleaning which have led to the abandonment of this device by other makers. The coils are wound with five sizes of wire graded according to calculation, and this is said to increase the sensibility as 9 is to 4. The clearance between the coils is 1-20in., and connection is made by the plugs and wire R. The mounting of the coils is, however, very inferior to that of the English instrument. A nut V screws down upon two halves of a coned seat, as shown in Fig. 1; while it will be seen in Fig. 2 that the coil is held by a separate screw G on a separate pillar yoked to its neighbour. The terminals B are provided with ebonite washers D to keep dust out of the hole G of the case; as in Messrs. Nalder's instrument, which contains exactly the same device, these are withdrawn when the instrument is in use. Spirit-levels are not only abandoned, but attention is called to this fact in the description of the galvanometer—"the instrument being usually levelled up until by inspection of the mirror the system is seen to swing freely."

The use of bell magnets in constructing the needle system is, of course, public property, and while Messrs. Queen and Co. have acted wisely in adopting this feature, it is a pity that they have gone back to the old and erroneous idea that a large moment of inertia is desirable in ballistic galvanometers. So prevalent was this notion at one time that we should hardly have been surprised to hear that a ballistic galvanometer is so called because a ball of lead is

Hosted by Google

sometimes attached to the needle. Bell magnets are invaluable for ballistic work, where constancy is essential; but filling them with lead, as is done by Messrs. Queen and Co., is objectionable for several reasons. A stronger supporting fibre is needed, and this entails a strong control, the very thing to be avoided. It also diminishes the sensitiveness for discharges by increasing the moment of inertia; this quantity, indeed, is said to be "extremely large." Mr. Willyoung, the writer of the description, and electrician and electrical engineer to Messrs. Queen and Co., claims this as an advantage. It is true that the inertia lengthens the period of swing, and lessens the decrement; but with bell magnets properly hung, this is usually quite small enough, and sometimes too small for convenience in working. The sensitiveness of this galvanometer is described thus: "Mean deflection 1-16 M.F. at 1·44 volt. . . . 237mm.; period, single swing, 21·6 seconds.' But in the absence of information about its resistance or the scale distance, this tells us little or nothing. If the scale distance be a metre, the sensitiveness at a given period is nothing remarkable, and, in the absence of any definite information from Messrs Nalder Bros., we believe we are right in saying that it is somewhat less than one-half of that afforded by their bell magnet instrument of about 8,000 ohms.

A feature of novelty in this galvanometer is the control. It will be seen in Fig. 1 that the outer magnets, *ns* and *ns*, are longer than the middle magnets, *sn* and *sn*. If all are magnetised in the same way, the stronger will control the system. A nut of soft iron, W, is capable of being screwed up or down on the lowest magnet, on the cylindrical surface of which a fine screw thread is cut. When it is down it is inoperative, but if it is desired to diminish the control, the needle system is removed from the instrument and the nut is screwed up. This has the effect of short-circuiting the magnetic field and thus weakening the control, making the system more astatic. The rod Q on which the system is built is of quartz. To have to unship the needles every time the control has to be altered is a serious objection, especially when of so fragile a material.

It is satisfactory to find that attempts are being made in the United States to build really high-class instruments, and no doubt more originality will be forthcoming in future examples. In the meantime we may observe that Messrs. Queen and Co.'s address is Chestnut-street, Philadelphia.

THE GROUND RETURN.*

In the course of the discussion at the recent meeting of the American Street Railway Association, at Cleveland, Mr. F. S. Pearson, chief of the steam and electrical department of the West End Street Railway Company of Boston, brought up some points in reference to the ground return, which, from his long experience in this line, should prove of interest to practical men.

In small towns and systems where there are few cars running, Mr. Pearson thinks the ordinary method of returning the current through the rails and supplementary wire is sufficient unless the distance is great. On large roads, where the traffic is heavy, more return grounds than have been used heretofore will have to be installed. It was found so in Boston, and from lack of return feeders a great deal of electrolytic action was caused in the supplementary wire, and the West End Company is now putting up a large amount of overhead copper for return grounds, since the underground will corrode and rust away. There is no advantage in using iron, as the conductivity is only one-seventh that of copper. Originally the positive current was run through the trolley wire, but it was found that the action on the supplementary wires was too great, and so the negative was put to the trolley wire. It was not thought that there would be much less effect, as it merely transfers the action to another point.

In reference to water pipes, Mr. Pearson said that he did not have in mind any particular trouble with water pipes; but naturally, if there is a large volume of current going through the earth, it will take hold of a water pipe or a gas pipe, or any other pipe, and there will be an electrolytic action set up; and in any large railway system, if the attempt is made to use the earth for return ground by putting in ground plates in driven wells, or by putting them in the rivers, and the return current is not provided with a good metallic circuit, the current must inevitably injure the water pipes and all other pipes. The current, when it leaves the car, goes into the ground, and, taking a water pipe, may go a mile on that pipe, then leave it for a better conductor, the result being that the pipe will be corroded at this latter point.

As to using old rails for a return, the difficulty is to make a good joint. If the rails could be welded or soldered, this plan might work, but the joints could hardly be made in any other way so that they would carry the large volume of current without heating or corrosion. To joint the rails by copper plates would be a poor construction, as the iron and copper would form an electrolytic element and cause corrosion, even if no current was passed through the joint. The passage of the current would also heat the joint and cause further oxidation. In the early days of electric railroading an attempt was made to use the rail for a return current and not put in supplementary wires, but it was found almost impossible to maintain a joint of any sort. When a large volume of current is sent through the joint oxidation takes place, and the joint soon becomes worthless. This condition will exist no matter how large the joint is made, and if dissimilar materials or metals are used a local electrolytic action will also take place. With steel in contact with iron the effect will be produced in a lesser degree than with copper, and it will take longer for the trouble to develop. Old steel and iron cables had been used in the crossing of rivers and for connecting the supplementary wires from one side of the track to the other, but the objection to the cable is that it cuts away very fast. For instance, in one place seven ropes or cables had been put in and soldered thoroughly at each end, and in less than four months they were entirely gone. If the soil was comparatively dry and sandy this scheme might do for a while, but where it is moist and solid it is a question whether the cables will last long enough to pay for putting them down.

As a rule in track construction to-day, the West End road uses supplementary wires as well as bond wires on the rails, the former having a low resistance as compared with the bond wires and joints. The greater current passes on the supplementary wire and does not go through the joint. If the supplementary wire is cut and all the current is made to pass through the bond wire there is trouble, but as long as a good supplementary conductor is maintained the current will not pass through the bonded wire, the joints will remain cool, and there will be no great tendency to oxidation, especially if tinned rivets are used.

DIFFERENTIAL CHARGES.

In his interesting letter on the now burning question of how best to charge for a supply of electricity, which will be found in our Correspondence columns this week, Major FLOOD PAGE raises a side issue, which has doubtless occurred to many of our readers, namely, whether an electricity supply company is, by the original Act of 1882, and apart from its Provisional Order, permitted to introduce either a system of discounts to large consumers, or a more or less complicated sliding scale. We do not propose to recur to the general question of electricity supply charges while the discussion is at its height, but as this issue is an interesting one, some comments thereon may not be out of place.

The technical press was recently very solemnly and very properly rebuked for hinting in a weak moment at the possession of some slight acquaintance with the laws of nature. We shall not, therefore, lay any claim to any special knowledge of the inner workings of that complex product of nature, the lego-parliamentary mind, but a careful perusal of Sections 19-20 of the Electric Lighting Act of 1882, especially if coupled with a glance at their expansions in Electric Lighting Orders, will, we think, set at rest any doubt as to the perfect right of a supply company to introduce any method of charging it thinks fit, provided always that the maximum is not exceeded, that the consumer consents, and that there is no "undue preference." A company may, therefore, announce with a clear conscience that it will charge places of worship, say at 50 per cent. less than the ordinary rate; but an announcement to the effect that it will only grant these favourable terms to the Church of England would be *ultra vires*, being not merely differential but preferential. In connection with Section 19 of the Act of 1882 a curious point arises in regard to the

Hosted by Google

difference between a "private" and a "public" supply. The definitions in Section 3, Sub-sections 3 and 4, though eccentric, are clear enough, and it is perhaps unfortunate that they should have been obscured by subsequent Provisional Order accretions and expansions, though of course they cannot be over-ridden by them. A "public" supply was, by Sub-section 3, confined to street, church, theatre and public hall *lighting*, and did "not include any other purpose to which electricity may be applied." A "private" supply, according to Sub-section 4. included "any purposes whatever to which electricity may for the time being be applicable, not being public purposes, except the transmission of any telegram." Hence current supplied to a fan-motor in a theatre would be a "private" supply, but not the current supplied to the footlights, and the energy supplied for blowing the organ or for working the action would fall in a different category from that used for lighting a church. The exact nature, under this definition, of a supply for the purpose of charging a storage battery is a nice point, which we leave for the study of our readers.

Considerations of a very different character have suggested the desirability of distinguishing between electrical supply for lighting and for motive power and heating. It is hoped that these applications, which were hardly thought of by practical engineers at the passing of the Act of 1882, will enable the plant of the supply stations to earn something during the day; and the complications of day and night meters, and special two-way switches have been thought worthy of trial. Such contrivances may be of use in encouraging the use of motors and of electrical cooking at the present time, but the necessity for any distinction at all seems to indicate that the whole supply business is as yet in an undeveloped state, and though it is highly improbable that motors will ever become quite as common in this country as in America, a small approach to the conditions which obtain in that country would render useless all the ingenious devices of meters and of double prices. "It will be noted," says the *Electrical Engineer* of New York, referring to the proposed "Manchester" method of charging, "that in the above calculations Dr. HOPKINSON has not taken into consideration the question of supplying current for electric motors, which, so far as this country is concerned, is a source of revenue practically not calculated upon abroad; and as the rates for power per kilowatt hour in the United States are greater than those obtained for the same amount of current when used for lighting purposes, a considerable modification in the calculation would be introduced." The futility of arguing from American to English practice is very clearly brought out in these half-dozen lines. On this side of the Atlantic we have to stimulate our motor load by 50 per cent. reductions, and do not do very much at that. In the States, on the other hand, the electric motor can, it seems, be made to yield a higher rental per kilowatt hour than the incandescent lamp.

SPARKING AT COMMUTATORS.

BY F. M. WEYMOUTH.

(*Continued from page 161.*)

In Figs. 4 and 5 herewith is shown a simple armature coil in a field between two poles **N** and **S**, which may be revolved about an axis $x\,y$. Now in Fig. 4, where the coil is shown quite vertical, and so with its plane normal to the lines of force running from **N** to **S**, if the coil be rotated in either direction, by which motion the number of lines of force it encloses is being *diminished*, a current will run round it as shown by arrow heads. Its polarity also (similarly as in Fig. 1) will be as indicated by the small s and n. In the case of Fig. 5 however, the coil is represented by the curved arrow as rotating from a horizontal position to a vertical. It is thus *increasing* the number of horizontal lines of force that can pass through it. The result is that a current will course round it, but in the opposite direction to that in Fig. 4. Now a point to be noted is that in Fig. 4, the n and s poles of the coil are *attracted* by the respective **N** and **S** poles of the field that they oppose, and hence will offer opposition to the rotation of the coil. In Fig. 5 also, it will be seen that in conjunction with the direction of rotation, the s and n poles of the coil are being brought nearer to the **S** and **N** poles of the field, from which they are naturally repelled. Hence here also there is opposition to the revolution of the coil. The opposition to the rotation, which in these cases is the necessary cause of the current in the coil, and so of the polarity of the coil, thus illustrates Lenz's law, that *any primary cause for an induced electric current produces effects which tend to eliminate such primary cause.*

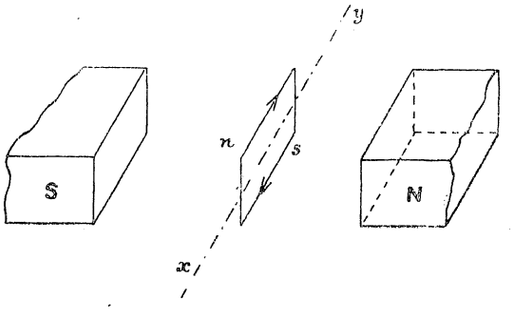

FIG. 4.—Lenz's Law Illustrated in Elementary Dynamo Coil.

We may now return to Figs. 2 and 3. It should be mentioned first that the iron core is supposed to be without magnetism when there is no current flowing round it. In Fig. 2 we find the sudden influx of the primary current causing the lines of magnetic induction within the core to rise in number from zero up to a certain maximum. This increase in the lines of *magnetism* is now the real cause of the current generated within the outer secondary circuit, running round in the opposite direction to the primary, as shown by the arrow heads; precisely as an increase is a cause of such an effect in Fig. 5. The result of this again, is that the secondary current tends to produce poles s and n, which are contrary to the primary: that is, to eliminate the very influx of magnetism by which the secondary current is itself called into existence.

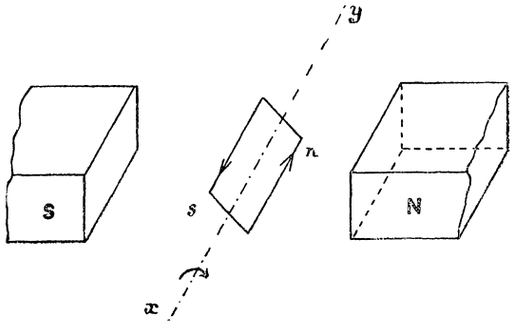

FIG. 5.—Lenz's Law Illustrated in Elementary Dynamo Coil.

Now while the primary coil may be of a few turns of stout wire, the secondary may be of a large number of turns of fine wire. The potentials of all the turns of the secondary being accumulated, forms an enormously high total electromotive force between the ends of the secondary, brought near together as at g. This distance not being disproportionate to the electromotive force, a disruptive spark will strike across in the direction of the arrow heads at the instant of the sudden increase of the magnetism of the core. The primary current continuing steady, and there being no further alteration of the magnetism of the core, there will be no continuance of current in the secondary, and nothing more will happen except that

Hosted by Google

the full strength of the primary current and the polarity of the core become established after the cessation of the resistance thereto offered by the secondary. But if the primary circuit be now suddenly broken, there will be an immediate decrease of magnetism in the core, from maximum to zero. This will cause a current to flow round in the same direction as the primary, as shown in Fig. 3, contrary to the manner in Fig. 2. A disruptive spark will fly across at *g* again, but in the opposite direction to that in Fig. 2. The secondary here will cause a polarity identical with that of the primary. It hence tends to maintain the primary polarity, while it is to the very fact of the *decreasing* of this magnetism that it owes its own existence. We thus see in these two cases a still further exemplification of Lenz's law as above enunciated.

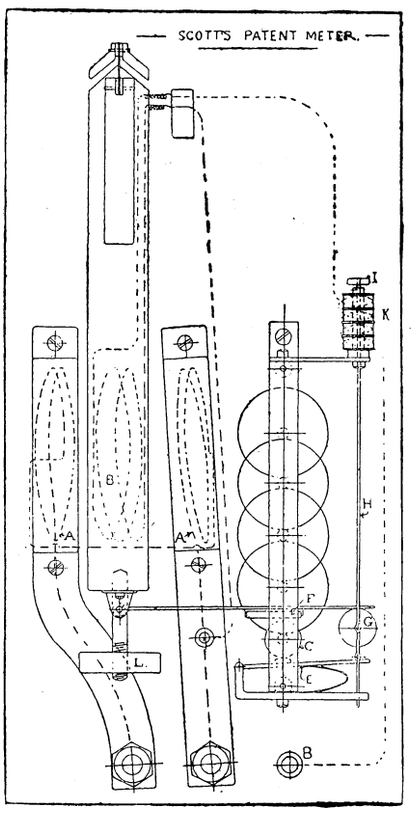
Now the sparks that take place at the gaps *g* in Figs. 2 and 3 are induction sparks pure and simple, such as belong to our second order. They are disruptive, and would do more damage to a dielectrical substance in the gap than to the terminals either side. As explained, their electromotive force would be very high, and the current extremely small. The potential difference however between the terminals will depend, as in the case of an armature winding, on the *number* and on the *rate* of the increase or decrease of magnetic lines, and on the number of turns in the secondary coil. Thus with a given rate of making or breaking the primary circuit, a compound coil, large in diameter so as to enclose many magnetic lines, and with a great number of convolutions in the secondary coil, will obviously generate a much higher electromotive force than one of smaller size, and with fewer turns in the secondary. Transformers, or converters as they are variously termed, exemplify this kind of conduction. A low tension *alternating* large current in the primary coil, consisting of a small number of turns of *thick* wire or copper bar, induces an alternating high tension small current in the secondary, having a large number of turns of *fine* wire; or *vice versâ*. The resistance caused by the fine wire, it will be noted, keeps the secondary current small, though its electromotive force may be high. In the high-tension experiments by Messrs. Siemens Bros., and Messrs. Swinburne and Co., at the recent Exhibition at the Crystal Palace, wherewith pressures of 50,000 and 130,000 volts respectively were attained, it was in this manner that such results were arrived at. Powerful disruptive sparks were emitted between electrodes; while owing to the presence of an appreciable current also, enormously long arcs, 2ft. or so in length, could be maintained. It is further to be noted here also, that owing to the normal potential being already so high, preliminary contact between the carbons was not required. The precursory spark of the arc was of our fifth order, and not our third order as is usual with the arc. For here, on the carbon points being brought within about 3in. of each other, the current would immediately leap across, after the manner of that order, with which we shall deal in due course.

As we have stated, however, the above refers to induction sparks only, which are caused in a *different circuit* to that of the primary. But sparks similar in nature, and based on the same laws, may be obtained in the primary—that is, within any circuit itself. Such sparks, with cause and effect taking place within the same circuit, are the result of what is called the *self-induction* of that circuit, and we may hence style them self-induction sparks. These, forming the sparks of our third order, may thus now engage our attention.

(*To be continued.*)

SCOTT'S ELECTRICITY METER.

The advantages of a clock-driven meter are so great, while the trouble of winding by hand and the complication and expense of automatic winding are so serious, that Messrs. Laurence, Scott and Co., of Norwich, propose to arrange one clockwork apparatus in a central position, and to control the timing of a number of meters by a special meter wire laid with the supply mains. An advantage of the system is that it enables the rates of charge for supply to be made different at different times of the day. The meter itself is fairly simple, as will be seen from the accompanying rough diagram, which shows all the working parts. Fixed series coils of strip copper A A carry the main current. A suspended shunt coil B, the resistance of which is about 1,500 ohms, carries an adjustable weight L. A terminal, B, connects this shunt to the special meter wire. These meter wires, which are arranged to take some 45 meters on each circuit, are connected at the station or at the meter station by a clock once in every 90 seconds. The effect of making circuit with the meter wire is to work the magnet K; this lowers the roller G, and allows the pad F to fall upon the wheel C, the first wheel of the meter train. The deflection of the suspended coil B measures the energy supplied, and the forward movement of the pad F, being a measure of this deflection, imparts a proportionate motion of the meter train, successive forward movements being integrated by it. The mechanism lifts



the lever F off the wheel C before the suspended shunt coil B swings back to zero. We are informed that these meters have an accurate range of 100. The central controlling clockwork is arranged to make contact with a number of separate meter circuits one after the other, and for long distances it is proposed that groups of meters may be worked by means of a relay. At any arranged time, say an hour before sunset, the clockwork can be arranged to alter from a period of 180 seconds to a period of 90 seconds. During the daytime, therefore, the meter registers half the current or any other desired fraction, and by this means a cheap daylight supply may be provided. Messrs. Laurence and Scott suggest that this will encourage the use of power, not only during the day, but will afford special facilities for power during the summer time, which might induce manufacturers who have steam power to use the electric supply during the summer months, and to run their steam-engines during the winter, utilising waste steam for warming their premises.

Royal Society.—The following Paper was down for reading yesterday before the Royal Society: "The Electromotive Properties of the Skin of the Common Eel," by Prof. E. Waymouth Reid.

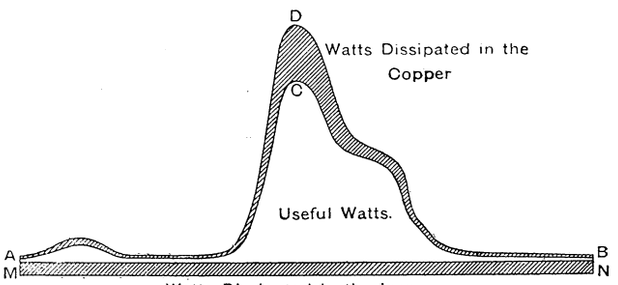
THE EFFICIENCY OF TRANSFORMERS AND TRANSFORMER DISTRIBUTION.

In a lucid communication recently made to the Société Internationale des Electriciens, M. R. V. Picou deals in a commendably succinct way with the *pros* and *cons* of transformer distribution, and, although the subject has been somewhat overdone of late, it is by no means exhausted, so that a brief summary of M. Picou's remarks may prove of some interest.

The alternate current transformer, says M. Picou, is, when considered by itself, an excellent piece of mechanism, but nevertheless its all-day efficiency when used in the usual way is comparatively low. The reason of this is, of course, well known. Of the 5 per cent. loss which occurs at full load, that due to hysteresis, which is more than one-half of this total loss, is an absolutely fixed quantity at all loads. The copper losses, on the other hand, vary as the square of the current. Hence numerous devices for securing a better average efficiency.

The following diagram was then given by M. Picou to illustrate the normal condition of things in a transformer distribution network. The curve A C B represents the paying load for an average day of 24 hours, the ordinates being watts. The area A C B A is proportional to the receipts. To this area two more may be added, giving a total area equivalent to the total output. Below A C B A draw a rectangle A B N M, the height of A M being equal to the watts wasted in hysteresis at any moment; A B N M, therefore, represents the energy wasted in hysteresis during the 24 hours. Next increase the ordinates of the curve A C B by an amount representing the total copper losses at any instant; the area contained between the curves A C B and A D B will then represent the energy wasted every day in the conductors, transformer coils and regulating resistances. The ratio of the ordinates of these two curves is evidently constant. The ratio of the area A C B A to the area M A D B N M gives the all-day efficiency of the system. A glance at this diagram shows in a very striking manner the dead weight of the iron losses at times of low load, when the copper losses are negligible.



Some engineers have had the idea of increasing the *average* efficiency by sacrificing something of the *maximum* efficiency. All economies effected in iron losses, of course, diminish the height of A M. If these economies go hand in hand with increased copper losses, the ordinates of the curve A D B are naturally raised; so that the *net* gain is represented by the difference between the sums of the two areas A B N M and A D B C in the two cases.

Two noteworthy solutions of the problem have been proposed by Swinburne and Dolivo-Dobrowolski respectively, both of whom propose to decrease the volume of iron. In the "Hedgehog" transformer the iron has been diminished by simple suppression. There can be no manner of doubt that the hysteresis loss is thereby also diminished, since air is apparently perfectly magnetically elastic. But let us look at the other side of the account. The power dissipated in such a transformer on open circuit = E C cos ϕ, and it is less than the power E C′ cos ϕ' dissipated in a closed magnetic circuit transformer. But as ϕ is much larger than ϕ', cos ϕ is much smaller, so that although we have C cos ϕ < C′ cos ϕ' the diminution of cos ϕ is such that we have C > C′. Consequently the primary current of a "Hedgehog" transformer for any given load is always greater than in the case of a corresponding closed magnetic circuit transformer, and the difference is accentuated at no load.

Now, if it were only a question of a single transformer it would be an easy matter to increase the size of the wires somewhat, and in this way to keep the copper loss constant and obtain the full benefit of the reduction of the iron loss. But when a transformer is considered as part of a system of distribution, the dynamos and conducting network have to be taken into account. Conductors traversed by larger currents waste more energy, so that we should appreciably increase the ordinates of the curve A D B, and there is nothing to prove that the final result will be economy. In fact, the net outcome of the compromise varies according to the average diurnal load, and a given transformer may result in a profit in one instance and in a loss in another.

Dolivo-Dobrowolski's solution of the problem is to reduce the volume of the iron while still maintaining the closed circuit. To push the induction density would not do, since, according to Steinmetz, hysteresis losses vary as $B^{1.6}$. To reduce the volume of the iron it is accordingly necessary to keep down the length of the magnetic circuit to just that figure which leaves sufficient room for the coils, and the gauge of the wires composing these must also be reduced; hence the copper resistance is augmented, since the number of turns has to remain the same. Hence, as in the case of the "Hedgehog," reduction of the iron loss has its counterpart in an increased copper loss, and the advantage gained by any given proportion of iron and copper depends entirely on the average output curve, and it may, indeed, become negative for a curve showing a high average.

Dolivo-Dobrowolski's solution is not, therefore, a general one, and becomes even less so on close inspection. The increased copper resistance impairs the property of self-regulation which arises from an extremely low secondary resistance. Modern practice is to arrange for a 2 per cent. fall on full load. Dolivo-Dobrowolski replies to this objection by remarking that since a central station has to have potential regulating apparatus in any case, why not extend their range to cover a 6 per cent. drop in the transformer? But this reply is not to the point. If the transformers were grouped together in sub-stations such regulation could, indeed, be effected; but the necessity for it would not then arise, since the iron losses could be kept down better by varying the size of the group to suit the load. On the other hand, with a transformer in every house the thing is impracticable. For instance, if one house has every light on, and the next one to it only a few, how is the matter to be dealt with from a central station?

In short, it is no use looking only at the transformer; we must take the *ensemble* into consideration. What are we aiming at? Evidently to obtain a high average efficiency for the system of distribution. Let us, therefore, get an expression for this efficiency and see what it teaches us. Let W be the iron losses in watts, C^2R the *total* copper losses; then the useful watts generated at a pressure E equal E C. The efficiency of the system of distribution is:—

$$\rho = \frac{EC}{EC + W + C^2R}.$$

The efficiency ρ varies with C, and if we inspect the function we see that it is susceptible of a maximum. This was, of course, to be predicted, since conductor efficiency decreases and transformer efficiency increases as the load rises. The condition of maximum efficiency is $W = C^2R$. The engineer should, therefore, arrange matters so that this equality of iron and copper losses is attained for the average current. There is no need to touch the transformers since, from a practical point of view, it is far easier to adapt the cross-section of the conductors to the circumstances of each individual case, than it is to first fix the size of the cables and then design transformers applicable only to the single case dealt with.

M. Picou concludes by giving it as his opinion that the Swinburne and Dolivo-Dobrowolski solutions of the problem are not happy ones; they show how a man may deceive himself when he confines his attention to a piece of apparatus and considers it apart from the conditions of its use. The *organism*, not the single organ, should be studied.

NOTES ON THE EFFECT OF HARMONICS ON THE TRANSMISSION OF POWER BY ALTERNATING CURRENTS.*

BY HENRY A. ROWLAND.

In a recent number of the *Johns Hopkins University Circular* and the *Phil. Mag.* for July, 1892,† I have shown that an iron transformer introduces harmonics of the periods 3, 5, 7, &c.‡ times the fundamental period into the currents and electromotive forces both primary and secondary of a transformer, and that these increased in value as the iron was more and more magnetised.

It is my present object to call attention to the effect of these harmonics on the transmission of power and its measurement. For lighting purposes they are evidently of very little significance, as currents of all periods are equally efficient in producing heat. There is a loss, however, in the fact that they cause more loss of heat in the wires and the iron of the transformers. But for the transmission of power the case is very different. Here the motors are designed to run at speeds dependent on the period ; if there is more than one period the adjustment fails, and there is a loss. The harmonics are thus useless in the transmission of power by synchronous motors, and are of very little use in motors with revolving fields. In these cases the harmonics travel around the circuits, heating the wires and the iron without producing valuable work. They then represent an almost complete loss in the transmission of power, and as they may contain 10, 20, or even 30 or 40 per cent. of the current, according to the magnetisation of the transformer, they are probably responsible for some loss of efficiency in many cases, as will be shown further on. Indeed, I believe they are the explanation of many seeming mysteries in the working of alternating current motors. Special arrangements of condensers and coils can be made to pick out these harmonics, so that they are more important than the original period. This may occur accidentally and cause many curious results in the working of motors.

It is, then, of the first importance in the transmission of power that the curves shall be pure sine curves and dynamos.§ Transformers and motors must be designed in the future with reference to this point. It would seem, also, that most calculations on the efficiency of power transmission by alternating currents must be at fault unless they include the action of the harmonics.

As to the amount of loss from this cause it is difficult to decide in general. With synchronous motors the harmonics simply flow around the wires without producing useful current of any kind. But this may not cause great loss if the resistance is small. Indeed, considerable distortion may represent small loss of power in certain cases, and great loss in others, according to the difference of phase of the current and electromotive force in the harmonics. In the case of motors with rotary fields the harmonics produce fields revolving with velocities 3, 5, 7, &c., times the primary field. Now, it is essential for the efficiency of these motors that the armature shall revolve nearly as fast as the field, and hence the efficiency for the harmonics must be very small indeed, and this must decrease the efficiency of the apparatus as a whole. As to the heating of the wires by the harmonics, it is easy to see that the total heating due to all the currents of different periods will simply be the sum of the heatings due to each of the currents separately.

The effect of harmonics on the hysteresis is much more complicated, and can hardly be calculated without further experiment. However, the following hypothesis may give some idea of the action. Let the primary electromotive force be considered unity, and let a_3, a_5, &c., be the electromotive forces of the harmonics. If these acted separately on the hysteresis the total would be

$$1+3\,a_3^{1\cdot6}+5\,a_5^{1\cdot6}+\ldots$$

Again, if they all combined so that the maximum electromotive force was equal to the sum of them all, the hysteresis would be nearly

$$(1+a_3+a_5+\ldots)^{1\cdot6}$$

However, it is hardly probable that this last condition would be often satisfied, in which case this formula would give too great a value. When the harmonics are small this last formula can be written nearly—

$$1+1\cdot6\,(a_3+a_5+\text{etc.})$$

As an example, suppose $a_3=0\cdot3$, and $a_5=0\cdot2$, and $a_7=0\cdot1$, these two formulæ give—

$$1+3a_3^{1\cdot6}+5a_5^{1\cdot6}+\text{etc.}=1+0\cdot44+0\cdot38+0\cdot18=2\cdot00,$$
$$1+1\cdot6\,(a_3+a_5+a_7)=1\cdot96.$$

Strange to say, the two formulæ agree for this special case in making the hysteresis nearly twice that due to the primary current. The current heating is only—

$$1+a_3^2+a_5^2+\text{etc.}*$$

Or, in the example—

$$1+0\cdot09+0\cdot04+0\cdot01=1\cdot14.$$

It would seem, then, that the loss due to hysteresis may be much increased by the harmonics, while the increase of current heating may be small. I believe the statement has been made that the form of the curve does not influence the hysteresis. This is evidently incorrect, unless we take the top of the curve to reckon from, in which case the statement agrees with the second hypothesis given above, if the harmonics are of the proper phase.

To estimate the influence on the efficiency of a plant, assume the efficiency of the dynamo and synchronous motor with primary currents as each equal to 90 per cent., and of the two transformers equal to 93 per cent., and assume that all the currents have the same harmonics as given above. The total efficiency will be 70 per cent. If the harmonics are now added, and half the 30 per cent. loss be due to conduction and half to hysteresis, then the efficiency will be decreased to 60 per cent. nearly, a loss of 10 per cent. There is too much assumption about this calculation to warrant full belief, and the figures are given more as a challenge to further investigation than as facts. That there is a decrease of efficiency is certain, but the amount must be determined by further experiment and mathematical investigation. But, however small the loss, provided it occurs in the transformers or the dynamos and motors, it may be of great consequence on account of its heating effect, because the output of these is limited by the amount of the heat generated.

The practical conclusion seems to be that transformers and the armatures of dynamos to be used in the transmission of power must be designed for low magnetisations. By experiment with transformers I find immense distortion of the curves when the induction exceeds 12,000 lines per square centimetre, while the curves are comparatively smooth with only 5,000 ; hence I scarcely think it advisable to use more than 5,000 for transformers even though low frequency were used. As to dynamos and motors, the limit will depend on the variety of machine used, and will not influence the better class very much.

The fixing of the limit of magnetisation of transformers at 5,000 causes the output with given current to vary *directly as the frequency*. As the hysteresis with slow frequency will be less, we may increase the current somewhat to make up for it. As to the exact law, it depends on the relative dimensions of wire and iron. Practically, we might estimate for an ordinary transformer that the output varied as the eight-tenth power of the frequency.

The law that the output varies as the four-tenth power of frequency assumes that the magnetisation increases with decrease of frequency, and thus distorts the curves as shown above.

The immense increase of the size and cost of transformers when distortion of the curve is avoided precludes the use of very low frequencies even were it otherwise desirable.

It is to be noted that the action of the iron in producing harmonics is directly on the electromotive force, and the amount of current flowing will depend on the resistance and the self-induction of the circuit. The resistance, owing to so-called "skin" effect, will be greater for the harmonics than for the fundamental period. Self-induction depending on the air will always diminish the harmonics, while if it is due to iron it may either increase or decrease them according to their phase.

The measurement of the energy supplied by an alternating current is also much complicated by the presence of harmonics.

Let the current be

$$C=A_1\sin(b\,t+\phi)+A_3\sin(3\,b\,t+\phi_3)+A_5\sin(5\,b\,t+\phi_5)+\ldots$$

and electromotive force

$$E=B_1\sin b\,t+B_3\sin(3\,b\,t+\psi_3)+B_5\sin(5\,b\,t+\psi_5)+\ldots$$

The energy transmitted is, then, per unit of time

$$\int_0^1 CE\,d\,t=\tfrac{1}{2\pi}\int_0^{2\pi} CE\,d\,(b\,t)$$

If n is the number of complete periods in the primary term, then $b=2\,\pi\,n$ and the energy transmitted per second becomes

$$\tfrac{1}{2}\,[A_1\,B_1\cos\phi+A_3\,B_3\cos(\phi_3-\psi_3)+A_5\,B_5\cos(\phi_5-\psi_5)+\text{etc.}]$$

An ordinary wattmeter in the form of an electro-dynamometer with non-inductive coils would give the correct value of this quantity, but any attempt to multiply the mean electromotive force by the current and the cosine of the phase would lead to an incorrect result unless this was done for each harmonic separately.

* From the *Electrical World*.

† See also the *Electrical World* of July 9, 1892.

‡ The periods 2, 4, 6, &c., can evidently be introduced by magnetising the iron of the transformer in one direction by a constant current, or having it originally with a symmetrical magnetic set.

§ Dynamos and motors introduce the odd harmonics on account of the variations of the self-induction of the machine, which become very apparent when a strong current is flowing. The armature reactions may also introduce the harmonics.

* This formula assumes that the resistance is the same for the harmonics, whereas it is greater on account of the "skin" effect.

Hosted by Google

It is to be noted that the introduction of condensers to balance self-induction will only work for one period at a time. Indeed, very many of the results hitherto obtained by observers will require modification in the presence of these harmonics. It would seem from the above that the transmission of a current for electric lighting is quite a different thing from the transmission of a suitable current for motors. It will be remembered that the transmission in the Frankfort-Lauffen experiment was one of a lighting current alone, and that some mystery seems to hang over the motor tests. Can the presence of these harmonics have anything to do with this?

EXPERIMENTAL RESEARCHES ON ALTERNATE CURRENT TRANSFORMERS.

The following is an abstract of the discussion of Dr. Fleming's Paper on "Experimental Researches on Alternate Current Transformers" which took place on December 1st and 8th at the Institution of Electrical Engineers. Speakers whose remarks are prefixed with an asterisk have returned their abstract revised :—

* Mr. J. SWINBURNE said that Dr. Fleming had found fault with the damping arrangement in his voltmeter. His firm had considered the question of putting oil or glycerine damping arrangements, but they preferred the electro-magnetic method, and the damping arrangement worked all right; but Dr. Fleming had not used enough current. These voltmeters were originally asked for, and ordered for, 1,200 volts, and he believed they were used on the 3-voltmeter method up to 3,500 volts, which was, of course, too much for a voltmeter designed for 1,200 volts. A very large factor of safety could not be used in these things, or there would not be sufficient force. He had, last year, discarded the arrangement of putting mica to prevent sparking, as anything of that sort might give trouble in calibrating with direct currents through small charges settling on the outside of the dielectric. Those instruments were really designed as electrostatic wattmeters, not as voltmeters. Turning to the wattmeter, he had now for something like five years urged that people should test power in transformers and things of that sort by means of a simple wattmeter. He had been ridiculed pretty much the whole time for it. It seemed impossible to get anyone to realise that a wattmeter would do it. If he took a wattmeter to a professor he immediately said, "That can't work. Let L be the self-induction and R the resistance and you get a reading which is a function of R and L." You say that does not matter. If you work it out and see what the value of L is you say it is so small that there can be no error. "Oh! no, that won't do at all. You bring a ridiculous little instrument that will read the power without any trouble whatever; we cannot have that; it is not scientific at all. What I really want is something like the Hampton Court Maze, made up of as many instruments and cross connections as possible." The errors that arise in that case might be pointed out, but that did not matter in the least; probably the result was entirely swamped by errors of calculation as Prof. Fleming showed, but that did not matter, and if they had something that they could call the cosine of the angle of lag it would be all right. Dr. Fleming has shown, however, that the 3-voltmeter method was not accurate in those cases; neither was the 3-ampere method. The 3-voltmeter method was first thought of by Prof. Ayrton and Dr. Sumpner, and he believed he had the honour of first publishing it while they were thinking about it, or after they had thought about it; but he pointed out at the time that he considered the thing merely a scientific curiosity, and that it could not be of practical value, because errors of observation would swamp out the power they wanted to determine. Now to go back to the 3-voltmeter and those methods; of course, the great difficulty was supposed to be the non-inductive resistance. It had been suggested that they took that wattmeter from the time it was merely a little watt-scope, and educated it up on purpose to read power low—educated it up as a sort of scientific witness with a big retainer to give evidence in favour of the Hedgehog transformer. That wattmeter was wrong, undoubtedly, and the error arose thus :—The first wattmeters were tested very carefully, very much as Dr. Fleming had done. Instead of a glass case they afterwards had a metal case of thin brass, and it did not seem at first as though it produced any effect whatever. Dr. Fleming had said the fine wire was not right—there was an inductive circuit. However, that could not hold, for the instrument read too little instead of too much, so it could not be an inductive circuit. The real cause was the Foucault current in the thin brass case of the first wattmeter sent. When the main current is lagging a quarter of a period, the Foucault current in the brass case is exactly opposite the E.M.F., and this lessens the reading. He certainly thought that a properly wound non-inductive resistance was more trustworthy than incandescent lamps. The first thing Dr. Fleming had shown was that the wattmeter was really an accurate method of testing power. That swept away at once the whole of the complications and difficulties in testing power. Anyone could make a wattmeter in which the self-induction or time constant of the fine-wire circuit was practically *nil*. The next point that he settled definitely was that with practically all transformers they could get the efficiency at full load and at various loads, if they knew the resistance of the circuits and the loss at no load; that is to say, the loss in iron remained practically constant throughout the load. The third point which Dr. Fleming did not settle was that question of the open circuit *versus* the closed circuit transformer. The real result was that the particular transformer which had been sent him was bad; but he did not mean to say that they happened to send a bad transformer, and that the rest of their transformers had losses of only 20 to 30 watts. They tested the iron first; it was no fault of the iron. Dr. Fleming first suggested, and he adhered to it still, that it was due to the eddy currents in the copper. As a matter of fact, removing the secondary circuit altogether made no difference whatever. He suggested also that it might be due to the phosphor-bronze core; they tried one without a phosphor-bronze core but it made no difference. Also that it was due to the castings at the end of the transformers; they tried one without castings, but there was no difference. It was only quite recently that they had hit upon the real cause of the abnormal results in these Hedgehogs. If a 10lb. pull was maintained on the wire while a Hedgehog was being wound it resulted in something of the order of 30 tons pressure on the core. The core was composed of small iron wires, so well insulated that if two of them were twisted together the resistance between them would be something in ohms. But it had not occurred to them that when many tons pressure was put on these wires perfect contact was made; and that was the whole of the difficulty; it was simply Foucault currents in the core. They knew now what was wrong, and were very much indebted to Dr. Fleming for showing what was wrong.

He protested against Dr. Fleming's doctrine of power factors. A great many transformers which had really closed iron circuits might have power factors upon which they they might depend; but in the case of the Thomson-Houston, or those made by Brown, Boveri and Co., there was a joint made in the circuit, and very small variations of that joint would cause very large variations in the power factor. In the beginning of the Paper Dr. Fleming pointed out a consideration which was really as essential as any other, and that was the question of price of transformers. As Dr. Fleming said, anyone can make an efficient transformer if he puts enough money into it; that was an important point, and so was weight. They could not bring that into the discussions of a Society like theirs; but it was, of course, a very important matter. Dr. Fleming did not seem to appreciate that the back E.M.F. which caused the drop in the transformer was a quarter of a period out of step with the real E.M.F., so they had to take the square root of the sum of two squares. The effect of that could be very easily seen. If they took a transformer whose inductive drop was 1 per cent. and put it on an inductive circuit, the drop was 15 per cent., that was because they then had to subtract one from the other, instead of squaring them and taking the square root of the difference.

* Prof. GEORGE FORBES alluded to a series of tests of a Westinghouse transformer at Pittsburgh in the year 1888. He had been extremely surprised at the remarkably high efficiency of those transformers, even at that date with a small output. The points which everybody had been aiming at in the design of transformers in the past had been to make the efficiency at low loads as high as possible; but when the houses which took electric light were much more closely grouped together, they would have sub-stations with much larger transformers capable of regulation either automatically or by hand. Then the efficiency of the transformer at low load would not be of so very paramount importance. If they were content to have a high efficiency at the very large loads, then they could put in a much smaller amount of copper, and a certain larger quantity of iron. That was, of course, a cause of enormous reduction in the cost of transforming. In the case of a transmission of power the cost of the transformer was very great indeed. The cost of the transformers for transmission of power from Niagara to Buffalo, according to the estimates put in up to the present time, was considerably in excess of the 5,000 h.p. dynamo which produced the current, and consequently the two transformers were nearly three times the cost of the dynamo which was generating the current. He thought it would come out something between one-half and one-third of the cost of transforming if they were not made in the way they had been made for lighting purposes, but so as to give a high efficiency only at full load.

* Mr. GISBERT KAPP : Dr. Fleming had been at great trouble to investigate the accuracy of the 3-volt meter method, and preferred the wattmeter. At Frankfort all measurements were made by wattmeter, and these instruments had been standardised in various ways, and the measurements were as accurate as possible. He had made a great many experiments with the 3-voltmeter method, using the same instrument for the three readings, by switching over into the mercury cups. He found at first that the method seemed to be very inaccurate, but that was simply due to errors of reading. He had made a test on a transformer wound with very stout secondary copper, 512 mils. × 120 mils., and then exactly the same core wound with a thin wire, and curiously enough the transformer which had the stout copper gave about 120 watts total loss, including hysteresis, and that with thin wire gave 130, so he did not believe it was in the copper. It was generally assumed that transformers at one-twentieth of their output had a very poor efficiency but it was shown by these tables it was quite possible to have transformers with 75 per cent. at one-twentieth of their full load, and as much as 85 per cent. at one-tenth of their full load. That was very important as affecting the all-day efficiency in central station working.

The PRESIDENT asked Mr. Kapp whether the transformer he referred to as being one with thick copper and thin copper was an open circuit transformer or a closed magnetic circuit transformer. Secondly, was the thick copper next the iron or the fine wire next the iron. Next, which had he magnetised?—the iron with the inner coil, or the outer coil, because that would make a total difference in the answer.

* Mr. KAPP : A closed-circuit transformer. The thick copper was next the iron, the thin copper was outside that, and was not used in the test at all. The power was supplied at 100 volts to the thick copper in one case, and then a precisely similar carcase was taken again of closed magnetic circuit, and wound with very thin copper. He thought it was 120 mils. diameter, exactly the same number of turns and exactly the same relative position as the thick copper in the real transformer; but the copper was

Hosted by Google

not wound quite close to the iron. It was a transformer very much of the same kind as those made by Brown, Boveri and Co. to which Mr. Swinburne had referred. The copper was wound on a separate sleeve, and slipped over the core.

Mr. SIDNEY EVERSHED alluded to the very early days of the Gaulard and Gibbs transformer, when Prof. Ferraris carried out a number of experiments, showing that the losses in the core actually fell off. Those experiments received some support from Dr. Fleming himself; he gave an abstract, and a very appreciative abstract, from him in his book on alternating-current transformers. Next in the controversy was Mr. Mordey's experiment with the shilling thermometer and the Mordey transformer. Shortly after that Prof. Ayrton made experiments of a similar kind, and confirmed those results. In the meantime, in America, Prof. Ryan had practically solved the whole question. He experimented in a totally new way on a live transformer, and those who had read his results—and he was sorry to say not very many English engineers took much notice of what was done in a scientific way in America—felt that Prof. Ryan had practically settled the real question of transformers for all time. He showed what the rate was and what it ought to be, and other things. A little while after that Mr. Swinburne published his Paper at the British Association, in which he put down all the essential points in the design of transformers. Americans took up that Paper and Prof. Ryan's work, and he rejoiced to see that the transformer which came out at the top of the tree was American and not English. They deserved to be left behind in that race, and the Americans deserved to succeed. His own calculations of the losses in various transformers about three years ago came out almost exactly identical with those now tested by Dr. Fleming. He found a good closed circuit transformer might have an efficiency of about 94·5. If the magnetic circuit of that transformer were opened its efficiency would be raised to 96 per cent.—a very small rise indeed; but at one-tenth the full load a closed circuit transformer had an efficiency of 85 per cent., that was to say about as good as the best of those tested by Dr. Fleming. But that transformer, when it had its magnetic circuit opened, as he plainly showed, would have an efficiency at one-tenth of full load of 89 per cent. if there were no eddy currents or coils. He could not help thinking that that estimate of difference between open and closed circuit transformers, only 2 or 3 per cent., was more likely to be near the truth than those estimates which Mr. Swinburne gave from time to time. Mr. Vignoles and he had carried out a small experiment, only an indirect one, but it proved quite conclusively that there was no falling off in the loss, as a transformer was loaded up. It was rather curious that nobody took any notice of either Prof. Ewing's results or his own, and the tide only turned when Dr. Hopkinson published some experiments carried out on a similar plan to Prof. Ryan's and showed that first of all there was no viscous hysteresis, and secondly the losses in transformers could be calculated if the cycle the iron went through was known.

* Mr. W. B. SAYERS sent a written communication in which he observed that at the time of writing he had seen only so much of Dr. Fleming's Paper as had been printed in the technical papers for the week ended November 25th. He suggested that just as a rapidly alternating current tended to flow more through the outer portion of the metal of the conductor so conversely did a rapidly alternating magnetic flux tend to limit itself to the skin of a mass of iron through which it was passing. It would appear that calculations of the losses in transformers cores which did not take into consideration the increased density of the magnetic flux due to the crowding towards the surface of the plates might be, more or or less, erroneous, according to whether the plates were thicker or thinner, or the frequency higher or lower. Might not this crowding action be largely the cause of the divergence between actual observed losses due to magnetic hysteresis and the values calculated from Prof. Ewing's results, on the supposition that the magnetic flux was uniformly distributed in the core plates of transformers?

Mr. EVERSHED remarked that the whole of that question of eddy currents in laminæ had been gone into by Prof. J. J. Thomson and also by himself, and it was shown that the effect of the eddy current in crowding the induction to the outside was very small. In an extreme case the induction at the centre of the lamina might be 2 per cent. less than at the outside.

Sir David Salomons then exhibited an alternator, which was described in our last issue.

THURSDAY, DECEMBER 8TH.

Mr. MORDEY, resuming the discussion, alluded to his experiments which had shown a decrease in the iron losses at full load. He remarked that the question was not so important as it appeared to be thought, for, if he was right, and if the losses in iron did decrease with the loads, it only affected the efficiency at full loads, or at considerable loads, whereas the great and important question on which this battle of closed *versus* open circuit, this question of transformer distribution generally, had been fought, was the question of losses at no load. It was merely a question of money to get transformers so good that the losses at no load were negligible. There was a very proper feeling in that Institution against the advertising of the wares of any particular firm or manufacturer; but they must remember that this was a Paper intended for the assistance of practical manufacturers, and practical manufacturers were not in business for their health; they were in business for commercial purposes. They used a certain letter L, and if they put one horizontal cross on the £, it was "bad form." Mr. Mordey then described a number of experiments made on transformers with the view of observing the sudden rush of current on closing the circuit. He first used a 5-H.P. Ferranti transformer on the 2,400 volt mains from Trafalgar-square. On the same mains there were many transformers in use in customers' houses, so it could scarcely be a capacity effect. Then a 100-volt lamp was put in series with the primary of this transformer, the secondary being open, and the primary circuit was closed rapidly. Out of 47 contacts there were seven bad "rushes" of current, and a number in which there was a minor rush, a considerable increase over the normal magnetising current. Loading the secondary circuit made no difference. Then a 20-H.P. Ferranti transformer was put on and tried in the same way. Sixty contacts were made, there were five or six small rushes of current, and then the last contact broke the lamp by an extremely violent rush. With one of his own transformers there were only two or three trifling rushes of current. He made 400 contacts with a 5-H.P. Ferranti transformer, and got no effect at all at 100 ∿, whereas, at the London Electric Station, at 83 ∿, the effect was very marked and frequent. After other experiments, he tried making very quick contacts by tapping one wire against another, and got a very violent effect indeed at 50 periods. These experiments showed that there was a relation between frequency and time taken in switching—the lower the frequency the worse the result. He thought if, by gradually breaking the circuit, he could draw out the curve so that the following waves gradually decreased until they were very small, that he would leave the residual magnetism very slight indeed in the transformer. A number of trials fully confirmed this supposition. Slow breaking, following by slow making, never showed any effect at all. He wanted to see if the effect penetrated to the secondary, that was to say, whether a large wave of current set up a large wave of magnetism. He put a 16-c.p. lamp on the secondary and found no such effect. It all depended upon what part of the wave they made the contact at. He thought that he had better make an experiment that had probably occurred to everybody who had read the paper as a way of settling that. He took a small 1-ampere 1-c.p. lamp, and put it in with several transformers and a secondary battery to supply the current, so as to get the following wave in either direction he liked, and he found that that confirmed the explanation which Dr. Fleming had given, that when he made the contact in the same direction as the previous current, the lamp took about a second or a second and a-half to incandesce; when in the opposite direction it took four or five seconds to incandesce, showing that the current had to work out the previous magnetism and set its own going before it could assume the steady stage.

* Mr. R. E. B. CROMPTON said that he had consistently held one opinion, and that was that the system of distribution of energy by means of alternating currents had yet to be improved to a very considerable extent before it could be at all useful or at all likely to compete with the older and simpler methods which were now so successfully employed in this country. About five years ago he first started this subject. It would astonish some of those gentlemen who were so confident of the success of alternate transformer distribution if they were to turn up and read the discussion that then followed. He then gave a figure of the consumption of fuel for current sold, which had never yet been reached by any system of alternate current distribution in the world. And there were gentlemen there who could state that they had far beaten the figures he gave for direct distribution. That was to say, the real progress during the last five or six years had been in direct current distribution, and that up to very recently alternating current distribution stood almost still. The causes of the difference between the two systems, no doubt, were chiefly due to the enormous difficulty of ascertaining where the losses really did lie in alternating systems of distribution. If he looked back on the six or seven years in which they had made such enormous improvements in direct distribution, he found it entirely due to the fact that from the first they had been able to measure and locate their losses. The only guide the engineer in charge of an alternating system at present had was the readings of his consumers' meters. If he wished to find out what would be the results of an economical improvement he found it very difficult to do so, because he had first to wait such a long period until the meters could be read. It might be convenient to state that the true economic efficiency of the best existing generating and distributing plant on both systems might, when worked under the best conditions, that was to say continuously at full load, in both cases reach the figure of 37, which represented the number of tenths of a pound of coal burned under such conditions. Now, whereas the best result actually obtained with continuous current plant was 64, leaving only the difference between 37 and 64 as the room for further improvement in this class of plant; in the case of alternating machinery the difference was between 37 and 160, leaving 123-10ths, or 12½lb. of coal per unit as yet to be accounted for. He believed that it would be found that nearly two-thirds of this loss was still in the transformers, and was principally due to the low-load factor conditions under which transformers were necessarily worked. Now, although Dr. Fleming showed in his Paper that modern transformers showed greatly improved results, yet even under the improved conditions the loss still would be very considerable. It was a mistake to believe that the load factor of a central station corresponded with the load factor at the transformer sub-station. As a matter of fact the load factor at those points would occupy a position lying between that of the central station and that of a private house, that was, between 14 and 5. The efficiency of the best transformers described in the Paper would be raised from 54 per cent., if fixed at the private house, to about 80 per cent. if worked on a load factor of 7 in transformer sub-stations; and the difference between these two figures represented the measure of improvement foreshadowed by the Paper.

* Dr. SUMPNER alluded to two methods of testing transformers given on the first page of the Paper, due to Dr. Hopkinson and to himself. The difference between the two methods was, that one was only suitable for the laboratory, whilst the other was suitable for use in works. His (Dr. Sumpner's) method was economical because it only required the amount of power which was wasted in the transformer, and it was economical not only in power but also in plant, because it only required, as Mr. Mordey had publicly stated, a 3-H.P. or 4-H.P. dynamo to test 40 or 50-H.P. transformers. The best method of testing a single transformer was to use a wattmeter to measure the losses occurring in the iron, and in the copper of the transform er

Hosted by Google

separately. He had always held the opinion that the wattmeter was both the simplest and most accurate means of measuring power supplied by alternating currents. He had gone into the theory of eddy currents in wattmeters, and taking two results which Dr. Fleming had given, he had been able to predict by calculation what the other seven or eight readings of that wattmeter were. Dr. Fleming himself was the first to point out, about six years ago, that when a piece of metal was suspended near a coil through which an alternating current of electricity was passing, the eddy currents induced in the metal were such as to act upon the suspended metal plate; and the explanation was also given by Dr. Fleming. He (Dr. Sumpner) had taken an ordinary Ganz wattmeter and used it to test the power given to condensers and choking coils, and tested whether bringing up a plate of metal near the coil altered the deflection of the wattmeter. He found that the deflection of the wattmeter was increased when it was measuring power supplied to condensers, and diminished when measuring power supplied to choking coils by as much as 70 per cent.

Mr. RAWORTH said that at Newcastle-on-Tyne, with alternating currents, they were paid for a certain number of units which were passed through the meters, and the coal which was used came to something like £20. At Liverpool, where they were at work at the same thing, they also used £20 of coal to produce these units.

Mr. ALBRIGHT observed that it must be a matter of common knowledge to anybody who knew what they did at Liverpool, that they practically did not use batteries.

The discussion was again adjourned, and will, we understand, be resumed on the first meeting of next year.

LEGAL INTELLIGENCE.

The National Telephone Company and another v. Graff-Baker.

The action brought by the National Telephone Company against Mr. Graff-Baker to restrain him from so using his electric cars at Leeds as to interfere with the use of the telephone came before Mr. Justice Kekewich on Tuesday. Sir Richard Webster, Q.C., M.P.; Mr. J. Fletcher Moulton, Q.C.; Mr. C. M. Warmington, Q.C., M.P.; Mr. Nath. Micklem, and Mr. R. W. Wallace; instructed by Messrs. Waterhouse, Winterbotham and Harrison, appeared for the plaintiffs. The Solicitor-General (Sir John Rigby, Q.C., M.P.); Mr. W. R. Bousfield, Q.C., M.P.; and Mr. Alfred Dunham; instructed by Mr. Clarence Leighton, appeared for the defendants. Mr. Morton Daniell, instructed by Mr. F. W. Kite, held a watching brief on behalf of the Thomson-Houston International Electric Company.

Sir RICHARD WEBSTER, in opening the case for the plaintiffs, said that he appeared on behalf of the National Telephone Company and a subscriber, of the name of Lupton, against Mr. Graff-Baker, the contractor working the electric tramways at Leeds. The action was brought in order to restrain the defendant from so using his tramways as to interfere with the convenient and ordinary use of telephones which had been established for a great many years at Leeds. He did not think there would be much dispute upon the facts, although, of course, there might be substantial argument as to the legal rights of the parties. The question was whether the defendant, without being legally liable, could so conduct his business as to interfere with the telephones. Counsel then explained at length the technicalities of the telephone and electric tramway. For upwards of fifty years the earth had been used as the common return for telegraphic messages, and that would be found to have a not unimportant bearing when he came to deal with the legal rights of the parties; because, as his lordship probably knew, it had been decided many years ago now in the Court of Exchequer that a telephonic message was a telegraphic message, and since that decision of the Court of Exchequer, which was a decision at the instance of the then Attorney-General, the telephones had been worked under a licence from the Post Office as part of the Government monopoly. It would not be suggested, and it could not be suggested, that the plaintiffs' use of the earth as a return did harm to any one. He believed he was under the mark when he said that nine-tenths of the telephonic business had been carried on with the earth return. The electric tramways at Leeds were worked under a Provisional Order, and except the authority to lay the rails down in the road, and authority for stables or depôts and things of that kind, there was no statutory authority for occupying the soil of the roadway with any telegraph posts or posts of any sort or kind. By Clause 16 of that Provisional Order it was provided, "the carriages used on the tramways may, subject to the provisions of this Order, be moved by animal power, and with the consent of the Board of Trade to be signified in writing during a period of seven years after the opening of the same for public traffic, by means of haulage with wire ropes or other appliances placed underground or by means of electrical power, pneumatic power, steam power, or any mechanical power." The Board of Trade had no power at all except in connection with the safety of the public. They had nothing to do with authorising any particular method of carrying out the work. It could not be suggested, nor was it suggested as a matter of law, that the statute authorising the Tramway Company to work by electricity in any particular method would in any way justify the defendants, if otherwise liable, in disturbing the telephones. In Section 51 protection was given to the Postmaster-General in respect to working tramways by electricity. It might be said against them, "You have not got any special statutory protection in this Provisional Order with regard to your telephonic wires." His answer would be at once that their rights depended upon the established principles of common law, and not upon any special statutory protection. It was a fact that in numbers of Provisional Orders which had since been obtained, Parliament had inserted express protection for telephonic wires; but, in this case, he was driven to rely on the rights at common law, and not on any special statutory protection. It would be proved, beyond controversy, that there were certainly two, if not more, means by which electrical power could be used without in any way disturbing the telephone wires. He did not admit that economy was at all a necessary part of his proof. It was no answer that if the defendants could only avoid doing damage by extra expense that was a justification of what they did. Perfectly independent people would give testimony that, speaking of the effect of the working of the cars on the telephonic circuit, it was to render the telephonic circuit for commercial and business purposes absolutely useless. His clients would be prepared to prove, from the point of view of expense, and from the point of view of facility of working, that the method of working by a return conductor would be as good if not better, and as cheap if not cheaper, than using an earth return. He must now address the Court for a very few moments on the law of the case He based his argument upon established cases, which enunciated the principle, in the first place, that no statutory authority could justify an interference with private rights, if that statutory authority did not involve the necessity of interference. The best case was *Vaughan* v. *The Taff Vale Railway Company*. In that case, where, without negligence, sparks came out of an engine, it was held by the House of Lords that where a statute allowed one to run locomotive engines, if the sparks came out without negligence, no action could be brought against the Railway Company. In the *Gas Light and Coke Company* v. *The Vestry of St. Mary Abbotts*, in 15, Queen's Bench Division, page 1—what was the case there? A gas company laid down mains; the mains might go through private property, they might go through the streets; they were lawfully there, but there was no obligation or any restriction as to the particular place in which the mains should be put. It was suggested by the defendant in that case that the mains might be sunk deeper, and that if the mains were sunk deeper, they would have nothing to fear from rollers. It was only a question of expense. The Vestry was minded to repair roads, and they wished to do that cheaply and quickly, and accordingly they used fifteen-ton and twenty-ton rollers, and the steam rollers in many places broke the pipes. It was held that inasmuch as it was not necessary for the defendants to do this damage, they were liable. If in that case the defendants had been expressly authorised by statute to use steam rollers of such a weight as necessarily to injure the plaintiffs' pipes, the plaintiffs would have had no ground of complaint. In the case of *Evans* v. *The Manchester, Sheffield and Lincolnshire Railway*, which is in the 36th Chancery Division at page 627, a canal, constructed under the authority of an Act of Parliament, was, in consequence of the working of a coal mine by somebody else, caused to subside. The water leaped from the canal into a mill. It was held that though the company was authorised by an Act of Parliament, and was not under the same liabilities as a private person, it was liable for damages if guilty of negligence, and that the canal company had been guilty of negligence, inasmuch as it might have prevented the damage, and was bound to compensate the mill-owner. In this case it was suggested it was not negligence, because some other person had undermined the canal. However, it was decided that the company had to keep the water in, and it was no good saying it imposed an extra burden. Sometimes it had been suggested that they required to have a property right. That was disposed of altogether in the case of *Ballard* v. *Tomlinson*, 29, Chancery Division. In the course of the case he would satisfy his lordship that, with clearly less cost, certainly with no loss of efficiency, the defendants could conduct their tramways by electricity if they were so minded. It was sufficient for his purpose to point out that they had no statutory power whatever to use any particular kind of electricity, or to use it in any particular way. They only had permission to use electricity. If they used it so as to interfere with and do an injury to persons who were lawfully carrying on business in which electrical currents were essential, he submitted that the action could be maintained, and he asked his lordship to remember that Mr. Graff-Baker and the Tramway Company could not say that the Telephone Company were interfering with them in the slightest degree. It made not the slightest difference to the tramways whether the telephones were there or not.

Dr. JOHN HOPKINSON was then called and examined by Mr. Warmington. Witness stated that he was consulting engineer to the plaintiff company, and proceeded to explain the *modus operandi* of the telephone to the Court. There must be a complete closed circuit, but it was not necessary that there should be an earth return. The Exchange system did not in the least bit alter the mode of operation. Currents used for telegraphy varied, of course, but were measured in thousand parts of an ampere. For traction purposes they had currents of 200 amperes, or 300, and figures of that magnitude. For lighting purposes it was not at all infrequent to have currents of 1,000 amperes. For telephones the currents were vastly smaller again than for telegraphs.

Mr. JUSTICE KEKEWICH: Give us some instances.—I do not know that I can. I do not know that they have been actually measured with any degree of accuracy, but I imagine they would be perhaps not more than the one-hundredth part as great, possibly not so great as that. It is the weakest for any public useful purpose.

Continuing, Witness stated that a current used for telegraphic purposes was exposed mainly to the danger that they might get a return of a lighting current by earth, if the return conductor was not insulated. Witness then explained to the Court the various methods of electric traction by accumulators, overhead trolley, underground conductor, with and without an insulated return.

Mr. WARMINGTON: Assuming that no one is interested other than the persons who are interested in the exercise of this traction power, simply from that point of view, which in your opinion is the most efficient and economically good?—In my judgment, that with the two conductors both insulated.

WITNESS said there were two or three reasons for that. First of all, there was the economy. In order to secure safety, the Board of Trade

Hosted by Google

required that the difference of pressure between a conductor and earth should not exceed 300 volts. The purpose of that was to ensure the public against serious shock. Now, if they used both conductors insulated, it was practicable to take out the current at 300 volts above the earth, and take it back at 300 volts below the earth, and in that case they had only the difference between earth pressure over each of the currents of 300 volts, so that they were able to work at an effective pressure of 600 volts, and therefore with conductors of half the size. Further, if with an earth return anything went wrong with the outgoing conductor the whole thing came to a stoppage. The most likely accident to arise was that one of the conductors should come into contact with the earth. With both conductors insulated no mischievous consequence would happen. They only had one line of defence broken down. At Buda-Pesth, where they had the double conductor under ground, they told him that they would not on any account be without it; they had found it of very great practical advantage. In order to disturb the telephone they must first of all have a variable current, and they had variable contacts with tramways between the trolley and the wire overhead, and between the wheels of the car and the rails. Every variation in contact caused a variation in the current, and that variation was at once reproduced upon the telephone in two ways. Then, again, they got variations in current from the commutator of the dynamo. With a return of uninsulated conductor through the earth, they got disturbances of earth pressure, and, in fact, a part of the current returning to the station, not by the rails and not by the non-insulated conductor, but through the telephone instrument, through the telephone line wire, and through the telephone receiving instrument. That was leakage disturbance. There were also disturbances due to electro-magnetic and electrostatic induction. There was nothing abnormal in the system adopted by the plaintiffs. It was the same system that was to be found in almost all the large towns in the country, and all over the world. He had tested some of the plaintiffs' wires for the purpose of ascertaining whether there was any disturbance by reason of the defendants' working. On November 13, 1891, there was a great deal of disturbance. On November 29th of this year, he tested some lines with Mr. Dalziel, the plaintiffs' manager. They went to the Leeds Exchange. They were connected in succession to a number of subscribers who were disturbed. He arranged them in order of loudness in four classes. In the noisiest class, which was an exceedingly noisy class indeed, he had three. There was 114, which was close by the loop; that was the call office of the Telephone Company. There was no mistake what it was which occasioned the noise heard. They could hear the cars start, and as the velocity increased the pitch of the note went up.

Mr. JUSTICE KEKEWICH: Applied to the ordinary purposes of commerce for which the telephone is largely used in commercial towns like Leeds, would it interfere with two business men carrying on their business communications?—Of course they can use every moment, and speak through when it is not quite so loud. I should say it would interfere seriously as regards the three first-named. What I should do as regards the other is, that I should always make a clerk talk for me. I would not talk myself—I certainly should not.

Continuing, Witness stated that the noise was in some measure, no doubt, caused by leakage; but the greater part of the disturbance was due to electro-magnetic induction. He had tried some special experiments to satisfy himself of that. All the numbers higher than 1,600 were connected to a subsidiary exchange at Chapeltown. From Chapeltown Exchange they were connected to the Leeds Exchange by cables underground, with an outgoing and a return conductor, both insulated; but to the Chapeltown Exchange the conductors were arranged on poles overhead. He tested the number of lines by dividing them, and satisfied himself that much the larger portion of the disturbance—not all of it, but the larger portion of the disturbance—was caused by electro-magnetic induction. Then he tried a subsequent experiment to satisfy himself that it was not electrostatic induction. In his opinion there was absolutely no difficulty in the defendants so constructing their works as to prevent the disturbance described. At Buda-Pesth there was altogether about 22 kilometres of single track. Six months ago they had 63 cars running, weighing 4½ tons each. In that case they had two conductors under ground, both insulated. There was no disturbance of the telephone excepting that they occasionally got an earth connection on one side, and then they did find a disturbance. He went to the head administrator of the telephone, and asked him particularly whether there was any disturbance. He had heard of nothing since the very start of the tramway. The plaintiffs, no doubt, could obviate the disturbance by duplicating throughout their wires.

Mr. JUSTICE KEKEWICH: Would the multiplication of wires in that way have any material effect in increasing or multiplying the risk of interruption and failure in the electric current?—No; I do not think it would make any difference. They would be quite as secure as they are now.

Cross-examined by Mr. BOUSFIELD, Witness stated that, as far as his knowledge went, it was the fact, broadly speaking, that nine-tenths of the electrical tramways in existence were worked upon the system which the defendants had adopted in Leeds. There was no difficulty in the Buda-Pesth system, owing to the fact that they had to work through a narrow slot into the conduit. At Buda-Pesth the slot was an inch and a third. It could be diminished to about an inch. Witness did not think that the diminution in the width of the slot would materially affect the efficient working of the system. The Vevey system would really be practically applicable to a place like Leeds. He had not thought much about the application of the Vevey plan to a complicated crossing, but the Buda-Pesth plan he had no doubt about. Witness was then handed a photograph of the crossing at Boar-lane, Leeds, and stated that he thought there should be no difficulty in applying the two-wire plan to such a crossing. There was no crossing whatever in Vevey.

Mr. BOUSFIELD: Do you know of any case where the system of double overhead conductors, either in the Vevey form or any other form, has been successfully worked out in practice to a complicated case of this kind?—No; neither successfully nor unsuccessfully. The only case of overhead conductors and an insulated return that I know of is Vevey, and in that case, as far as I remember, there is nothing but mere branches, which of course does involve a difficulty in an elementary form for the purpose of passing the cars.

Continuing, the Witness said that the system at Vevey did not give absolute immunity from noise in the telephones. He had never heard anything so bad in London as he did in Leeds, except a disturbance caused by the Grosvenor Gallery installation some years ago. In that case they had an open circuit. The Telephone Company complained, and they duplicated their circuit and cured it. He doubted whether in some districts of Leeds, quite out of the sphere of the working of the tramway, there were disturbances in the telephone as great as those caused by the tramway. Some of the tram wires were six feet from the telephone wires, and less in some places, even as low as three feet. If the telephone wires were taken twelve feet distant, then the disturbance would be vastly less.

Mr. BOUSFIELD: If your wire ran twenty feet off, that might possibly remove what is complained of?—It would very largely diminish it, undoubtedly; whether it would remove it or not, of course, I can hardly say.

Continuing, Witness stated that the telephone was perhaps the most delicate instrument in existence for detecting stray vibratory currents of electricity; but it was not a fact that in all cases a telephone without a metallic return was an extremely imperfect and unreliable instrument. One did hear a certain amount of disturbance from parallel lines, undoubtedly; but as to that, that amount of disturbance was not so great as to cause any insuperable trouble. It was true that even the ordinary telegraphic currents occasionally made serious disturbances in telephone circuits. On the line from London to Birmingham it was absolutely impossible to speak. He had never heard that for long lines earth currents had been found to be sources of interference. He had never had any experience of talking in London in which the noises were intolerable. He could not say that, owing to the delicacy of the telelephone, in every case where Her Majesty's Government erected telephones, they invariably used a metallic return, and not an earth return. He did not know that in the New York telephone system they had in all cases a metallic return. Neither did he know that the same was true of Paris, and of the New Telephone Company. In all long-distance telephone work a metallic return was used.

Mr. BOUSFIELD: Let me ask you this—it is perfectly simple, is it not, and feasible to have part of your system furnished with metallic returns and part with earth returns?—Yes. Of course, there are drawbacks in doing that, but it is possible.

So that here in Leeds this disturbance could be got rid of by duplicating the disturbed wires that I have pointed out and carrying them to earth near the Exchange instead of at the distant point?—Yes, I think you would get rid of it in that way.

So that at a comparatively small expense the Telephone Company could in that way make the system efficient, notwithstanding our tramway system?—I can hardly give you an estimate of the expense.

Comparatively small?—It would not be gigantic, I agree.

Supposing we did have metallic returns overhead for our tramways, as you suggest, there would still be some disturbance?—There might be a little, but it would be exceedingly small. I venture to say this, that at all events there would be nothing of which the Telephone Company would be justified in complaining.

We have a three-fold conductor, have we not, laid in the earth—the two rails and the copper conductor besides?—Yes.

So that 999-1,000ths of our current would pass along conductors and not pass into the earth?—I could not put any figure upon it, but no doubt a large part of it will go back to the rail.

At all events this I have got from you—that substantially the bulk of our current goes through our conductors, and not through the earth?—I should say so.

So we do not rely in any way upon the earth for the efficiency of the system?—No: I have tried to state that without the earth I think you could have a better system than you have.

Whereas you do, in fact, rely on the use of the earth at present for your system?—Entirely; we return entirely to the earth. We provide no special conductor for the return.

In continuation of his cross-examination, Witness stated he had not practically tested the truth of his hypothesis that the shaking of the trolley-wheels caused the current to vary. The cost of laying a slotted conduit-line would be about £2,000 a mile. If by Board of Trade rule the difference of voltage between the two suspended conductors was not to exceed 300 volts, then that would do away with the suggestion he had made. He had, however, ascertained from the Board of Trade that if an application were made to them to take the 600 volts, both leads being insulated, they would regard it with favourable consideration.

Re-examined by Mr. WARMINGTON, Witness stated both the length of parallelism and the distance apart were factors in the question of mutual induction between any two wires. With regard to the disturbance from the Grosvenor Gallery installation, which occurred some years ago, the Telephone Company complained they had a disturbance immediately the Grosvenor Gallery installation was started. The Grosvenor Gallery Company were working alternating currents, and it was found at once, on looking into it, they had a single conductor running out over a considerable circuit and coming back by another route. The Telephone Company suggested to them to run out their conductor, and then go back again by the same course or nearly the same course—within six or eight inches of the outgoing conductor. They did that and the disturbance was practically reduced to nil. With regard to the Vevey system, it did not appear to his mind that there was any insuperable difficulty in applying it to places where there were numerous crossings. The model put in, of course, gave rather

Hosted by Google

an extensive idea of complication, from the accident that the connections, as well as the insulated parts, were shown in the same way. At Leeds the problem to be solved *at present* was a vastly simpler one even than at Vevey, and beyond all comparison simpler than Buda-Pesth, where there was really a very complicated system of tramways. There would be no difficulty so far as Leeds was concerned in applying either plan.

The Court then adjourned until Wednesday.

WEDNESDAY, DECEMBER 14TH.

On the hearing of this action being resumed, Dr. JOHN HOPKINSON was re-called and examined by Sir RICHARD WEBSTER with regard to some photographs of the Buda-Pesth tramway

LORD KELVIN, examined by Sir RICHARD WEBSTER, stated that he had considered and investigated the question of the disturbance of the telephones at Leeds by the electric tramway. He knew of no cases in this country, except a part of the telephone system in Newcastle, and of no place in Great Britain or Ireland in which the metallic circuit was employed. Paris was the only place in Europe in which the double wire was used. He went on June 3rd last to Leeds for the purpose of examining the question. The disturbance was very severe. One could hear perfectly when the tramcar started and stopped. It made conversation almost impossible—for ordinary subscribers quite impossible. After explaining to the Court the way in which the Leeds line was worked, and his theory of how the disturbances arose, Witness stated that it was not necessary that a system of single insulated wire overhead should be used. There would be no practical difficulty in constructing a tramway in Leeds on the Buda-Pesth system. A question had been put as to whether or not the disturbances could not be got rid of by duplicating the telephone wires for a limited portion only of the circuits, and then taking the rest of the circuits to earth. He believed the disturbance might be cured for a particular subscriber by duplicating his wire and keeping his system wholly insulated, but that would be exceedingly inconvenient. He had reason for this view in the fact that duplicated wires, perfectly insulated wires, did get over the difficulty of ordinary induction disturbance, but when one point was put to earth the disturbances were immediately heard. He had tried it since the Court rose the day before. He went to the Central Exchange of the National Telephone Company in Oxford-court, and several cases were shown to him, taken according to what lines were free at the time, and in each case the most marked disturbance was produced by touching the previously insulated metallic circuit with a wire leading to earth. Practically nothing but an absolute and complete establishment of the telephone system throughout on the double wire would have the effect of curing. The Glasgow telephone system, a large one and earthed, worked admirably. A few times he had heard something like the Leeds noises, but not nearly so bad. That was due to the electric lighting of a train between Queen-street and Charing-cross.

Cross-examined by Mr. BOUSFIELD, Witness stated that the suggestion that, instead of taking the subscriber's wire to earth at his house, it should double back along the line, and go to earth near the exchange, would not be a cure. The electro-magnetic induction might be neutralised, but there would be an electrostatic effect. Witness was next examined at length upon the conditions of his experiments of the previous night, and admitted that he knew nothing whatever as to what the different disturbances on the route might be, and as to what disturbing element might be introduced into the system when he took the insulated circuit to earth. Nevertheless, the results obtained would be an auxiliary towards a theory. Cross-examined with regard to the Giant's Causeway tramway, Witness stated that there had been some complaints that one or two horses had met with their deaths from it. Country people came to get cured of rheumatism by touching the rails. He had touched the rails himself with wet hands and got a severe shock. That sort of thing could not happen at Leeds. Witness could not quite agree that where they had switches and crossings, and so on, they were a great deal easier to manage, and simpler with a single conductor than with a double conductor. He had no practical experience of the application of double conductors to the tramway system. Witness was next cross-examined on a model of a crossing on the double-wire overhead trolley system.

Re-examined by Mr. MOULTON, Witness repeated in detail an account of his experiments on the previous night. All was silent when he first put the telephone to his ear; then he spoke through to Birmingham to make sure. Then he stopped speaking and listened, and found perfect silence. Then the earth wire was put on. There was a loud disturbance. Then the wire was shifted and there was a loud disturbance. He heard the phonopore line from London to Leicester quite distinctly. Ten miles of the single phonopore line, which was a single insulated wire with earth return, was beside the telephone line to Birmingham. Of those ten miles for about eight the phonopore wire was within a very few feet (20ft.) of the telephone wire. There was only ten miles out of the whole distance that could be considered as practically near enough to produce disturbance, and yet, notwithstanding that, it was quite marvellous to hear the phonopore. There was no mistaking that it was the phonopore, because he heard the musical note, and the transmission of the musical note which gave the signals, according to the Morse alphabet, on the phonopore. He attributed that to the process of static induction by the duplicate circuit. With regard to the train at Glasgow which caused trouble to the telephones, electricity was supplied to it from outside through the central iron rail nearly midway between the two rails that carried the carriage, and the return was through the wheels on which the carriage rested.

Mr. EDWARD HOPKINSON, examined by Mr. MOULTON, stated he was Managing Director of the firm of Mather and Platt. He was requested on behalf of the plaintiffs to make an estimate for working the Leeds Tramway with insulated overhead metallic circuits. He worked out three different methods. First he followed out the line adopted in Leeds—that was to say, overhead conductors insulated, and a return partly through the earth, and partly through the rails, and partly by a conductor laid in the earth. Secondly, he worked out a double overhead conductor, all the conductors being insulated from the earth. With regard to the second method, he worked it out on a higher voltage—that was to say, 600 volts. Thirdly, with all the conductors insulated from the earth, but with a difference of potential of 300 volts between the two conductors, instead of 600, for the reason that 600 had never been actually sanctioned by the Board of Trade, and it was possible that they might take exception to the use of such high voltage. The amount of No. 1 estimate was £14,251, of No. 2 £12,698, and of No. 3 £14,665. That included boilers, engines, generators, cars with the motors upon them, and conductors, but no buildings or builders' work. He thought there was no doubt that the one of the two systems in which there was no connection to the earth would be the cheapest and most satisfactory in working, because if they had earth connections making use of the earth for the return there were various joints in the system, each of which was liable to introduce rust, which would increase in course of time by the oxidation of the joints and the actual wearing away of the tram lines themselves by the traffic, so that, although in the first instance it might be fairly satisfactory, it would, no doubt, tend to become less so in course of time. He had not in arriving at these amounts allowed for that defect in the first system. He had assumed that the defect would not exist. The prices were the prices at which his firm would be very pleased to obtain the contract.

Cross-examined by Mr. BOUSFIELD, Witness stated that, according to his view, the defendants were very foolish not to have adopted the second system. He was not aware of the Board of Trade regulation, which said that two overhead conductors near one another must not have a difference of potential between them of more than 300 volts. If that were so his second estimate then would have to be modified.

Mr. BOUSFIELD: Can you tell us why, this double conductor system being superior, you carried out the Bessbrook-Newry line on the single conductor system?—Yes, in that case it was desirable for many reasons to place the conductors approximately in the plane of the rails carrying the cars. There were other reasons which perhaps I need not go into, but in that case there are certain advantages with regard to simplicity in the single conductor which do not hold in cases where you have either conduit or an overhead conductor.

Are there not always certain advantages of simplicity obtained from the single conductor?—Certain advantages, yes.

Your firm, I think, put up the line at Giant's Causeway also?—My firm did not do it, but I superintended the erection personally.

That is also a single conductor?—It is.

Why was the single conductor preferred there to the double conductor?—I cannot give you the reeson in that case. It was the first railway I had ever put down, and it was put down under the supervision of Sir William Siemens, and I suppose for reasons of that kind which appear important he made use of his single conductor.

Your firm had to do with the City Electric Railway?—It had.

That is a single conductor, is it not?—Yes.

Can you tell me why in that case the single conductor system was preferred?—For exactly the same reason that I mentioned in the case of the Bessbrook and Newry Tramway. There it was desirable to have the conductor in the plane of the rails.

But you have got one conductor between the rails, have you not?—Yes.

It would have been just as easy to have two conductors between rails, so as to have the return independent of the rail, would it not?—No, it would not.

Why not?—There is great difficulty at the points and crossings.

That is where I suggest the difficulty comes in. Where you have points and crossings you do get a difficulty if you have a complicated system with two conductors instead of one—that is so, is it not?—In the case of the conductors being in the plane of the rails, not otherwise.

You have to have certain breaks and so on, whether they are in the plane of the rails or above the plane?—Yes.

After re-examination by Mr. MOULTON, witness withdrew.

Dr. JOHN HOPKINSON, recalled and further examined by Mr. MOULTON, said that he had seen the Leeds Tramway on three occasions. On the last occasion he carefully observed the cars as they ran on the rails in broad daylight, and in every case he could see sparks between the wheels and the rails.

Sir FREDERICK JOSEPH BRAMWELL, examined by Sir RICHARD WEBSTER, stated that he had been acquainted with telephone working ever since the introduction into England. Witness then gave evidence with regard to the general use of the single-wire telephone system in the United Kingdom. He had tested the telephone lines at Leeds with practically the same results as the other witnesses.

After some objections from Mr. BOUSFIELD, Witness was examined with regard to the Northfleet Tramway. With regard to the Buda-Pesth slot system, witness had not the slightest doubt that the slot could be reduced to a width of $\frac{3}{4}$in. With regard to the alleged complication at crossings which would be brought about by the adoption of the double overhead conductors system, witness did not think there could be any practical difficulty. There was one thing which seemed conclusive to show it could be done. The wheels of the tramcars on the defendant's system were the means which made the electric connection between the motors on the car and the rails, and the intermediate wire. Whenever they came to one of these complicated places, such as was suggested at Boar-lane, Leeds, they were compelled to have provision for these wheels to pass—that was to say, if passing was to take place. He could not see any greater difficulty in making a provision for the positive conductor to pass than in making a provision for the negative conductor to pass. If they could do the one they could do the other.

Cross-examined by Mr. BOUSFIELD, witness stated that he did not think he could say it was a fact that wherever, owing to any cause, there was a liability to disturbance by other electrical influences, the plaintiffs.

Hosted by Google

fell back on the system of metallic return. He did not know of any case of a long-distance line in which they had not duplicated their wires. On the other hand, he did not know whether there was a long-distance line which did not go near some telegraph wire.

Mr. BOUSFIELD: Then I think generally in any case where there is disturbance from some external influences, whether of other wires, or telegraph wires, or whatever it may be, the plaintiffs do fall back on the system of doubling their wires with a metallic return?—I am not connected with the direction of the Company, and I cannot therefore answer you, but I think I may answer you safely in this way, that wherever they find it desirable to have the double wires they use them. That I think I may safely answer you, and perhaps they possibly avoid expense to them and something more than expense. I am thinking of the great snowstorm of four or five years ago, and what did happen then, and what would happen now to overhead wires if they were doubled.

Perhaps, as you have mentioned that, you can tell us what the dividend of the National Telephone Company has been?—I ought to be able to, because I am a somewhat considerable shareholder, and perhaps I ought to have mentioned that before; when I say considerable, I mean considerable for a man of my means. I really do not remember what the dividend is.

It pays very handsomely at present?—I am glad to say it does.

And it might still pay handsomely if in certain disturbed places they doubled their wires?—I do not know. If you make a large capital expenditure and get no more return, my humble arithmetic points to a reduced dividend.

I believe the present dividend is somewhere about 12 per cent.?—All I know is the shares are only just at par—the £5 shares. I happened to be reading the paper while the Court was adjourned, and I happened to see the £5 shares have fallen seven-eights to 5⅛, which does not look like a state of bloated affluence.

As a matter of fact that commercial implement, Sir Frederick, even as you know it and use it in London, the earth return, is a very imperfect implement indeed, is it not?—It is a very imperfect one as compared with a complete metallic return, but you may buy anything too dear. The thing as at present arranged works, and works commercially.

Continuing, Witness stated, with regard to the Northfleet Tramway, the electric working had been abandoned. He was not surprised. It was a remote spot. Where they had a complex crossing, such as that which illustrated the end of Boar-lane at Leeds, the number of breaks in the two overhead conductors would be very considerable. It was perfectly practicable, notwithstanding that. He had never had to apply his mind to a case of that kind with double conductors, and to try to scheme it out so as to make a practicable tramway system out of it.

Mr. CHARLES LUPTON was then examined by Mr. WARMINGTON, and stated that he was a Leeds solicitor, and one of the plaintiffs in the action. His private residence was near the Roundhay-road. His telephone was No. 1,617. His office was in the centre of the town. Since 1889 he had been one of the plaintiffs' subscribers for No. 1,617. Until the defendants commenced running cars the service was very fairly satisfactory. Since November, 1891, it had become so difficult to use the telephone that practically he never used it unless somebody wished to telephone to him professionally. He heard a noise like a hum in the distance, which rapidly became more and more acute. It very often stopped and went on again. There was a breakdown in the defendant's works, and the cars did not run. During that period he could use his telephone quite as well as ever. When the cars started working again, the noise was as bad as ever.

Cross-examined by Mr. BOUSFIELD, Witness stated that he first complained to the National Telephone Company on December 15, 1891.

Mr. JUSTICE KEKEWICH: If it will help you for me to assume that the National Telephone Company and this gentleman, one of their subscribers, are working together in the most friendly way for the purpose of making their case technically and practically against you, I will make that assumption without anything further. I do not think you need prove that.

Mr. BOUSFIELD: I ask for the letters because they are undisclosed.

Mr. JUSTICE KEKEWICH: I will assume that Counsel advised the National Telephone Company that it would be better if a subscriber joined them as a plaintiff. They thought a solicitor would make a capital plaintiff.

Mr. BOUSFIELD: This was one of the cases where we were informed it was exceedingly trifling.

Mr. JUSTICE KEKEWICH: I venture to suggest to you that sometime during the Christmas holidays two gentlemen, one named by you, and one named by Mr. Moulton—competent men, not necessarily Dr. Hopkinson, or anybody else—should meet and try several of these places when the tramcars are running, and when they are not running, and be prepared to give me the result when we meet again in January. Between persons representing such large interests as you both do, there ought not to be the slightest doubt about this question of fact. The scientific and legal questions are two entirely different things. The facts ought to be beyond dispute.

Mr. BOUSFIELD: We have evidence in detail about these different things by our witnesses. I do not know that one differs very substantially from Dr. Hopkinson.

Mr. JUSTICE KEKEWICH: If they worked together as sensible men would, if two were to go and take care to have an hour while the tramcars are running, trying two or three places, and trying the same places in the hour after the tramcars have ceased, that given in evidence in the witness box would settle the whole question of fact.

Mr. BOUSFIELD: We will consider what your Lordship has said.

Mr. JUSTICE KEKEWICH: However, you go on, and cross-examine Mr. Lupton.

Mr. BOUSFIELD: I will only put two or three questions as to this.

Mr. JUSTICE KEKEWICH: You need not go into the question as to the union of the two plaintiffs; it is a thorough union of hearts, no doubt.

Dr. THOMAS RICHARD JESSOP was then called, and examined by Mr. WARMINGTON, and stated that he was a surgeon carrying on his profession at Leeds. He had been a subscriber to the plaintiffs' telephones from the beginning. Until 1891 he did not suffer from any disturbance. In November, 1891, when the defendants started their trams, he experienced very great difficulty.

Cross-examined by Mr. BOUSFIELD, Witness said the nuisance was not one people were likely to get used to in time.

On the Witness being re-examined by Mr. WARMINGTON, the following letter, dated November 15, 1891, and written by witness to the Telephone Company, was put in:—"Dear Sir: I desire to draw your attention to the very serious inconvenience that is experienced from the effect upon the telephone produced by the electric tramcars. The continuous loud hum heard whenever a car is in motion, almost precludes the possibility of hearing a conversation. To-day, Sunday, and on several occasions, I have not only been unable to hear anything above the loud buzzing of the car, but the effect upon my ear has been lasting and most unpleasant. During this week, since the line was opened, several of my family here complained, and to-day I have found that their complaints are well founded. I shall be glad to hear what your opinion upon the point is, and whether you think any remedy can be provided."

Mr. ROBERT MIDDLETON, examined by Mr. MICKLEM, also gave evidence as to the telephonic disturbances caused by the electric cars.

Cross-examined by Mr. BOUSFIELD, Witness stated he certainly did occasionally telephone home from his works, but that it was no uncommon thing for his orders to be misunderstood.

Mr. BOUSFIELD: I might tell your Lordship that our case is that there is disturbance, no doubt, but in no case is it such even in the worst cases as to interfere with the use of the instrument so as to make it useless.

Mr. JUSTICE KEKEWICH: Then of course you must destroy all the evidence I have heard. I should have thought, unassisted by your observation, that the great advantage of the telephone was to hear quickly what otherwise might have been transmitted at least as surely by message verbally or in writing, and that if anything interfered with the promptitude with which it could be done, it interfered with the advantage of the operation altogether.

Mr. BOUSFIED: I am not in a position to say there is not some interferance with the enjoyment of the telephone.

Mr. JUSTICE KEKEWICH: I have given you a pretty clear indication of where my mind is at the present moment.

The Court then adjourned.

THURSDAY, DECEMBER 15TH.

On behalf of the plaintiffs, Sir Frederick Bramwell, Mr. D. Sinclair, and Mr. W. H. Massey were called and examined. The last witness objected to overhead conductors altogether, and was in favour of underground conduits. This evidence closed the plaintiffs' case. The Counsel for the defence deferred his speech, and at once called Mr. George Wood, Water Works Superintendent, who stated that the telephone wires were everywhere connected to the water pipes; Mr. W. H. Preece, who gave evidence as to the freedom from disturbance with twin-wire metallic circuits; and Mr. James Swinburne, who described experiments he had made at Leeds, which showed that the disturbance was not so serious as was suggested. The case was then adjourned to January 12th. A full report of Thursday's proceedings will appear in our next issue.

Laurence, Scott and Co. v. Greenard.

In the Ipswich County Court, on Wednesday, Messrs. Laurence, Scott and Co. sued E. S. Greenard, manager of the City Clothing Company, for the sum of £1. 9s.

Mr. SISLING, manager of the plaintiff firm, explained that this was for renewal of lamps and breakages.

In answer to the Judge, the Witness said the verbal agreement was that the contract should be the same as with other customers, and as mentioned in the firm's circular. The firm never renewed the lamps, which were left to the care of the consumers in the same manner as gas burners.

His HONOUR: I do not see any analogy between the electric lamp and the gas burner.

Mr. SISLING contended that there was, though perhaps the electric lamp wore out quicker. In the previous year the defendant paid for a small renewal, and since the rendering of the disputed account had promised it his attention and made no objection.

The DEFENDANT said the bill he agreed to settle was for the supply of the electric light, and not for the renewal of any fittings. In the first instance he inquired most particularly of Mr. Sisling what the cost would be, and he told him £12 a year, to include everything. At first he only had one lamp, but when the firm put in others he paid the cost. He had never paid any charges of this kind. An inexperienced youth sent by the plaintiffs had attempted to make a little alteration in the wires when the current was on; consequently he burnt his hand and "knocked the whole thing over." On previous occasions, when similar charges were in the accounts presented to him by the plaintiffs, he had struck them out and paid only the residue of the account. He contended that these lamps were an essential part of the contract inasmuch as they contained the light itself, and the current was merely the motive power.

The JUDGE expressed the opinion that the necessary lamps and fittings were as much part of the light as the current itself. Unless it could be shown that the repairs had been rendered necessary by the negligence or carelessness of the defendant, he did not see that the latter was liable.

Hosted by Google

Mr. SISLING: It is the universal custom in the trade to supply only the current, and the consumer pays for the apparatus, which remains his property all through. We only supply electricity, and not light.

The JUDGE: The Act of Parliament and the public call you electric light supply companies.

Mr. SISLING pointed out that there were gas burners which largely corresponded to electric light lamps, and which the gas companies did not repair. All the other customers of the firm in Ipswich and elsewhere had renewed their lamps at their own expense, and often got double the light by so doing.

The JUDGE: It is perfectly clear that, at the time he took this from you, you were supplying electricity; he wanted light—he did not want electricity. These peculiarly constructed globes are as necessary to produce the light as electricity. There is no analogy between gas and the electric light so far as the burner is concerned. Gas will burn without any burner. If you turn it on to a plain lead pipe you can get a light. The gas burner is only an adaptation by engineers, or whoever make these things, to economise the gas. Your peculiarly constructed globes are a *sine quâ non*.

Mr. SISLING replied that the electric light might be obtained by a simple conjunction of wires.

The JUDGE: But you don't suppose a man will stand holding them together.

The DEFENDANT said he had had seven or eight renewals before the firm thought to charge him for one. They induced him to have the electric light by charging him nothing for the internal fittings, as they wanted to get the light before the public of Ipswich.

Mr. SISLING denied these statements; it was the external work which was put up at the firm's expense.

In the end judgment was given for the defendant, with costs, and in answer to Mr. Sisling's application for leave to appeal, his Honour said he did not think the appeal would lie.

Mr. SISLING: It is such an important principle, and the decision may have a disastrous effect on our business.

The JUDGE: Each case depends upon its intrinsic circumstances. Here you gave him to understand that you would keep up the electric light.

CORRESPONDENCE.

PRICE OF ELECTRIC SUPPLY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There can be no doubt that supply companies from time to time feel the pinch of the conditions under which they are compelled to supply the electric current. An instance which has been recently given by the Chairman of one of the supply companies furnishes an example of this. A consumer having a place wired for 600 lamps, the supply company are of course obliged to have engine, dynamo and boiler power, and mains, sufficient to furnish a supply of current for the whole 600 lamps whenever the consumer chooses to turn them on; yet, as a matter of fact, the consumer in question hardly ever uses more than 12 lamps at one time. A still harder case is that of a large hotel in the North of England, in which there are 1,000 incandescent lamps. The owners of the hotel have furnished their own generating plant. When the contractor was arranging the plant in question, he drew attention to the necessity of having a duplicate plant. "No," said the wise owners, "there is no necessity for our putting in duplicate plant, we will give notice to the supply company that we have an installation of 1,000 lamps." Of course, the supply company must be ready at any moment to pass current through their mains for the supply of the whole of these 1,000 lamps, although no one of them will ever be supplied with current from the source of public supply unless the internal arrangements of the hotel break down.

Baldly stated in this way, the supply companies would seem to have a grievance, but, whether they have or not, they must certainly dislike having so much capital locked up—in the one case practically without return, but in the other at an absolute loss—as their plant will not be earning anything for years to come.

To meet such and other cases, Dr. Hopkinson, the House to House Company and others, have suggested various modes of charging by which the severity of the pinch may be lessened, and all those interested in any supply companies have been considering these and other suggestions with a view to seeing whether there was any fair and legitimate way out of this difficulty, and whether they could induce consumers to take a larger and more regular supply of electricity by giving them a preferential discount for so doing. Mr. A. B. Holmes, of Liverpool, has, given us the advantage of his experience, and draws attention to the fact that in the Licence granted to the Liverpool Electric Supply Company in 1888 a sliding scale of charges was introduced. It is instructive that Mr. Holmes should write, "It was found, however, that the consumers had some difficulty in understanding the scale, being accustomed to the sweet simplicity of the uniform rate charged by the local gas company, and that dissatisfaction was always expressed by consumers who used their lamps only a small number of hours, and, therefore, never reached the lower rates." Again he says, "Four years' trial of the above method of charging in Liverpool proved that its disadvantages were greater than its advantages, and in the Liverpool Electric Lighting Order of 1892 the sliding scale was repealed, and a uniform rate of charge substituted."

This seems the probable final solution, and fixed and easily understood prices will prove the most acceptable, and after a time we shall almost certainly find that one uniform price will be charged throughout each district.

It is hardly a matter of question that the Provisional Orders cannot over-ride the Electric Lighting Acts of 1892 and 1888, under which these Orders are granted; and if a case ever comes before the Courts in which the Provisional Order gives certain powers which in excess of, or contrary to, those contemplated by the Electric Lighting Act itself, the Provisional Order will have to give way, and the conditions of the Electric Lighting Act carried into effect. Now, Clauses 19 and 20 seem to a layman absolutely to debar the supply companies from making preferential prices. As it is a very important question, and one which seems to have escaped attention, I think it advisable to quote these two clauses:—

19. Where a supply of electricity is provided in any part of an area for private purposes, then, except in so far as is otherwise provided by the terms of the Licence, Order, or Special Act authorising such supply, every company or person within that part of the area shall, on application, be entitled to a supply on the same terms on which any other Company or person in such part of the area is entitled under similar circumstances to a corresponding supply.

20. The undertakers shall not, in making any agreements for a supply of electricity, show any undue preference to any local authority, company, or person, but, save as aforesaid, they may make such charges for the supply of electricity, as may be agreed upon, not exceeding the limits of price imposed by or in pursuance of the Licence, Order or Special Act authorising them to supply electricity.

There may be a loop-hole in the words "under similar circumstances" in Clause 19, and the supply companies might think that a man who was using his maximum current daily was not being supplied under the same circumstances as a man who only used the tenth part of such current. I am afraid, however, that the words of the 20th clause might enable a consumer who was charged at the rate of 8d. per unit because he did not use as much current as his neighbour alongside, who was paying at the rate of 5½d. per unit owing to his using his maximum of electric current, to claim to be charged at the lower rate. It is a matter for lawyers to determine whether a small consumer under Clauses 19 and 20 of the Act could claim to be supplied at the same rate as a consumer who receives the preferential discount. My own experience shows that, while under certain circumstances a gas company is entitled to give a large consumer a preferential discount, yet in another case a gas company, which was most anxious to meet large consumers, declared that it was unable to do so from the terms of its Act, even to consumers using a most exceptional amount of gas.

The conclusion of the whole matter, therefore, seems to be that even if a preferential discount might legally be given to those whom all supply companies would recognise as the best customers, the difficulties of arranging these preferential charges, and the still greater difficulty of making the general public understand them, will render their working so difficult that the supply companies will follow the example of the Liverpool Electric Supply Company and have only one charge.—Yours, &c.,

S. FLOOD-PAGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The correspondence which is now going on in your columns on the various methods of charging for the electric energy supplied from central stations is of great importance,

Hosted by Google

not only to consumers, but especially to electric light companies. Broadly speaking, there are four methods in use: (1), the fixed charge of so much per unit, irrespective of the number of units supplied; (2), the same as (1), but with a discount to large consumers; (3), a sliding scale; and (4), a differential rate according to the purpose for which the supply is required. The last-mentioned method is in use at St. Pancras, and has been devised by Mr. Baron, the superintendent at that station. Under it a consumer requiring power as well as light must wire his premises with two distinct circuits, one for the power and the other for the light supply. In the former is placed a meter registering at 3d., and in the latter a meter registering at 6d., an ingeniously arranged switch being provided whereby the consumer can only get the cheap supply for the motor when he does not use the light; but if he wants to use the light at the same time as the motor, both supplies pass through the 6d. meter. This enables the consumer to get cheap electricity during the day, and is an advantage to the supply company, because tending to fill out the load diagram during the hours of light load. How far this object is attained depends on the relative importance of the two circuits. If the lighting circuit is of so much importance to the consumer that he must use it when he works his motor, then the supply company is certain to get 6d. per unit supplied to the consumer during the hours of heavy load; but suppose that the power circuit is of far more importance to the consumer than the lighting circuit, and that he can manage to do without the light at any time that he wants to use the motor, then the company has to supply energy at 3d., even during the hours of heaviest load, and this is, of course, very undesirable. What the company wants is not an increase of load in the evening, but a moderate and steady load all day long.

This object may be, but is not necessarily, attained by the St. Pancras system of metering, and it is only incidentally, if at all, attained by any of the previously mentioned methods of charging. It is incidentally attained when a discount is made to large consumers, because a large number of units cannot be supplied unless the time during which the supply is taken extends beyond the few hours during which the load diagram is highest; but there is no inducement to a consumer to take his heavy supply rather in the day than in the evening. Take the case of a manufacturer who uses light and power. If he knows that during daylight hours he gets his power for 3d. a unit, and that in the evening he is charged 6d., he will naturally so arrange his work that the heaviest jobs are done in the day and the light jobs or no work at all are done in the evening. But if he is charged equally in the day and evening, he will not trouble to organise his work in any other way than that which suits his own convenience, and thus his motor will increase the load at the station at the very time when the maximum number of lights in the district is in use. The discount system, therefore, whilst tending to increase the total business done by the company, also tends to heighten the peak of the load diagram, and this is undesirable. The same reasoning applies to the sliding scale, which is only a modified form of discount, and both labour under the disadvantages pointed out by Mr. A. B. Holmes.

In my opinion, the only way of charging which is attractive to the consumer and, at the same time, profitable to the supply company, is by supplying at a cheap rate in the daytime and at full rate in the evening. Whether the consumer uses the current for cooking, heating, lighting, or any other purpose does not concern the company. All that the company cares about is that he should use a good deal of current during the daytime and not too much in the evening, because in this way the load diagram will be filled out without its peak being raised. Thus, the company can do a larger amount of business without having to instal additional machinery; there is no need for complicated accounts which the consumer does not understand; he need not instal special circuits for the different supplies, and no switching over from one circuit to the other is required; and last, but not least, he requires but one meter, on which he can see at any time what amount he owes to the company in precisely the same manner as he has been accustomed to do with the gas meter.

As regards the apparatus required for effecting such a method of charging for the supply, there need be no great difficulty. It may be done in various ways, of which the simplest, perhaps, is a clock, which at predetermined hours throws a mercury switch in and out, thus shunting part of the current round the meter during the time that the cheap supply is given, or the clock may be arranged to periodically alter the speed ratio of the registering mechanism.—Yours, &c.,

GISBERT KAPP.

31, Parliament-street, Westminister,
December 10, 1892.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The interesting letter of Mr. Bromley Holmes in your last issue shows very clearly the disadvantages of basing a sliding scale of charges upon the maximum demanded supply when this is taken to mean simultaneous supply to all the lamps, &c., fitted on the consumer's premises, and it does not appear that the use of a maximum current indicator in connection with each consumer's meter, as suggested by Professor Kennedy, would quite meet all the difficulties.

We may suppose that, by using the heating effect of the current to operate the indicator, or by the use of a dash-pot, the indicator movement might be made so slow as to prevent the record from being seriously affected by a momentary increase in the current, such as would be required to blow a fuse. Otherwise an accidental short-circuit might considerably increase the price per unit for that unfortunate consumer for a whole quarter, and thus lead to undue friction with, if not to sparking at, the collector. It may be said, however, that the ultimate effect would be desirable, inasmuch as it would tend to the more general adoption of such arrangements as would almost abolish the chances of accidental short-circuits on any but the smallest branches, *i.e.*, at the lampholders, &c.

We may further suppose the indicator would be re-set at the proper time only, and after its reading had been duly recorded by a trustworthy inspector. Even then this system of charging, although it is sufficiently complicated to be troublesome in actual work, does not always tend to produce the effect required alike in the interests of the supply company and of its consumers, viz., a large load factor.

For instance, churches requiring supply on Sundays only would have to pay the highest rate, but it would be to the interest of the supply company that the rate should be reduced on Sundays in order to develop demand when a large part of the plant would remain idle if the higher price prevailed.

Similarly, during the two summer quarters business places and many other customers would have to pay the higher rate. The demand would thus be repressed in the summer time, when in the interests of the supply company it should be developed by reducing the charge. Shop windows would probably be kept alight if supplied at a lower rate after business hours, and motors would be more extensively used for intermittent work and purposes requiring supply for only one or two hours daily, if the supply were charged at a low rate, always excepting during the time of heaviest demand for lighting purposes. This would frequently result in arrangements being made to avoid taking supply just at this time, thus increasing the load factor.

From the concluding clause of Mr. Holmes' letter it might be supposed that in matters which affect the system of charging there is no essential difference between the supply of gas or water and the supply of electricity. It may, therefore, be well to refer to the differences. For convenience let that part of the total annual cost which is made up of interest on capital, depreciation, and such other expenses as vary very little with the duration of the demand, be called the fixed expenses.

In the supply of gas and water, owing to the cheapness of storage and the large variation which is allowable in the pressure at the consumers' terminals, a comparatively small increase in the fixed expenses enables the produce of the machinery to be delivered to consumers when required at about ten times the rate at which it is produced at the works.

In the case of electricity, owing to the lack of any efficient means of modifying the pressure, such as would be equivalent

Hosted by Google

to the reducing valve commonly used with branch gas pipes and burners, it is necessary to maintain the pressure within very narrow limits at the consumers' terminals. For reasons well understood the fixed expenses are proportional, not to the greatest consumption during a period of, say, two days, as in the cases of gas and water, but to the maximum rate of supply provided for, although this rate may be demanded for less than one hour in the year.

Consequently the problem of charges for supply is essentially more complicated in the case of electricity than in the cases of gas and water; and the central stations which are able to vary their rates of charge in such a way that their customers reap the benefit of fitting in their demands to produce a large load factor will, other things being equal, pay better dividends, and develop a larger and more varied demand than the stations with a fixed scale of charges.—Yours, &c., W. B. Sisling.

THE DISCUSSIONS AT THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I wish to protest, through the medium of your columns, against the gross encroachment made on the valuable time of the Institution of Electrical Engineers by some of its members speaking on subjects which are totally foreign to the Paper under discussion. At the last meeting of the Institution Mr. Crompton spoke for nearly a quarter of an hour on his own capabilities, and the advantage of the direct-current system, both, doubtlessly, subjects of intense interest to anyone who had never heard Mr. Crompton's views before; but I do think, Sir, you will agree with me that, when so able a Paper as Dr. Fleming's is being discussed, the above behaviour should not be tolerated.—Yours, &c.

J. Leslie Fuller.

THE REGENT STREET FIRE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Mr. Heaphy, in his letter of the 6th inst. in your last issue, has taken an exaggerated and erroneous view of my letter to you of November 28th. I made the remarks on what I believed to be reliable authority, but, as I am not permitted to publish the names of my informants, who, however, I may add, are not connected with Insurance Companies, I am bound to withdraw the remarks and express regret for publishing them.—Yours, &c., J. D. F. Andrews.

London, Dec. 13, 1892.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Tenders Invited.—The date for the receipt of tenders invited by the municipal authorities of Brescia, Italy, for the electric lighting of the town has been extended to January 31st.

——— The civil authorities of Turn-Leverin, Roumania, are inviting tenders until January 10, 1893, for the electric lighting of the town.

Tenders Accepted.—The tender of Messrs. King, Mendham and Co. has been accepted for the erection of the electric signals in connection with the Clifton Rocks Railway. The arrangements to be made include means for signalling, from the lower end to the top of the line, the number of passengers to be carried up the railway each journey, replying and starting signals, and telephones.

——— The tender of Messrs. Crompton and Co. (Limited) has been accepted for the lighting of the two Courts at the Shire Hall, Chelmsford, by the incandescent light.

——— At the last meeting of the Electric Lighting Committee of the Whitehaven Town Trust, it was decided to accept the tenders of the Locca Engineering Company for setting new boilers at the Whitehaven Central Station for £700, and the tender of Messrs. Higginbottom and Mannock was accepted for the supply and erection of an overhead travelling crane at West Strand, at £138. The Chairman explained that the crane was invented by Dr. Hopkinson.

Tenders Received.—The following is a complete list of the tenders received by the Wolverhampton Town Council for the electric lighting of the borough, the tender marked * being recommended for acceptance. The first eight tenders were for supplying the complete plant.

	£	s.	d.
Messrs. Siemens Brothers (Limited), scheme 1	27,105	5	0

Messrs. Reid Bros., arcs	2,240	0	0
Munro Manufacturing Company (Limited), switchboards	1,560	19	6

Plant for Sale.—Messrs. Wheatley Kirk, Price and Goulty have for sale three loco-multitubular steam boilers. Further particulars are given in our advertisement columns.

Sale by Auction.—Messrs. Garrod Turner and Son will sell by auction at 31, Carr-street, Ipswich, on Monday, 19th inst., at 12 o'clock, the electric light plant of the Ipswich Electricity Supply Company.

Partnership.—Mr. Joseph Kincaid, M.I.C.E., is about to enter into partnership with Messrs. Waller and Manville, and from January 1st business will be carried on under the style of Kincaid, Waller, and Manville, at 11, Great George-street, S.W.

Partnership Dissolved.—Messrs. E. Bohm and Co., carrying on business in Little Britain, E.C., as glass blowers and electrical engineers, have dissolved partnership.

Poole and White (Limited).—The first meeting of the creditors of this Company (in liquidation) is to be held on December 22nd, at 11:30, at the Inns of Court Hotel, Lincoln's Inn-fields, and a meeting of contributories is to be held on the same date at 12:30, at 33, Carey-street.

W. T. Henley's Electric Light and Power Company (Ltd.).—A meeting of this Company (in liquidation) will be held at Messrs. Ball, Baker and Co.'s, 1, Gresham-buildings, Basinghall-street, E.C., on January 16th, at two p.m., to receive an account of the winding up.

The Edison-Swan Company.—To meet the requirements of the provincial trade and shippers, it has been decided by the Edison-Swan Electric Light Company (Limited) to open branch depôts in the provinces, to be in charge of superintendents appointed by the Company. The advantage which the Company offers to the trade by this arrangement is that after January 1st next Ediswan specialities can be obtained, carriage paid, at the Company's depôts. Depôts are to be opened in Glasgow, at 153, West George-street; Dundee, 19, Castle-street; Leeds, 127, Albion-street; Hull, Carr-lane; Cardiff, 111, Bute Docks; and at Birmingham, Liverpool, and Newcastle. The positions selected for these depôts are central. As our readers are aware, no installation work is, or will be, undertaken by the Company.

Omnibus Lighting.—With reference to the lighting of the London General Omnibus Company's vehicles alluded to last week, it appears that about 70 omnibuses have already been fitted with the Bristol Electric Safety Lamp, and 140 additional are expected to be completed by the end of the year. The battery is charged from a small station fitted up near the terminus at Victoria, S.W., the current being taken from the Westminster Company's mains. The battery weighs about 8lb., and is placed in a wooden box under one of the seats. The box is provided with two brass spring terminals, which make automatic contact with the cells when they are placed in position. The lamp is of special manufacture, and is placed in the centre of the roof horizontally, thereby giving a maximum of light, and avoiding risk of breakage.

Electrical Company (Limited).—This Company are issuing a new catalogue of electrical fittings, &c., containing a number of new and original designs, some of which are of special excellence. A large choice is offered in electroliers, brackets, suspension lights, vestibule lamps, and lamps for office and general domestic purposes. The list also includes samples of a variety of glass shades.

Mr. Ronald A. Scott.—On Monday the 5th inst., Sir Augustus Harris placed an order with this firm to supply and fix a 30,000-c.p.

Hosted by Google

projector on the roof of the Palace Theatre, to be in working order at seven o'clock in the evening of the 9th inst. Over 200ft. of cable had to be fixed under awkward circumstances. The installation, however, was complete and the light running by the time specified.

RAPID TELEGRAPHING.—The *New York Daily Recorder* of the 8th inst. describes a smart piece of telegraphic work over the lines of the Direct United States Cable Company. An ordinary business inquiry was handed in at the New York Office by the United Press to the Central Press, London, and in 10½ minutes a reply was handed in to the General Manager of the United Press in New York. Quicker work has been done, not only by the Direct Company, but by other cable companies; but on this occasion no extraordinary effort was made, and the message was of an ordinary business character.

CHISWICK.—The clerk to the Local Board has communicated with the Board of Trade in reference to the arrangements with Messrs. Bourne and Grant for the electric lighting of Chiswick. It is stated that it will be necessary to advertise again, and the further consideration of the matter has, therefore, been adjourned by the Local Board for a month.

DOVER.—The agreement with the Brush Electrical Engineering Company has now been finally agreed to, and the Mayor at the last meeting stated that the Company had given a satisfactory undertaking as to proceeding with the work.

DUBLIN.—At the last meeting of the Corporation, Alderman Pile moved the adoption of the electric lighting estimate for 1893, at the sum of £10,180. 3s. He said it was unnecessary to make any provision out of the rates for this expense, as it was more than balanced by the estimated income and savings, the credit being £12,745, leaving a balance of £2,565. Mr. Mayne stated that, practically, the streets were lighted by the electric light for nothing, and the Lighting Committee were not disposed to stop with the 80 lamps at present in use, because the plant now at the central station would allow of an extension of the number of lamps. By a singular coincidence, immediately after the discussion upon the electric lighting scheme, the light went out, leaving the Council Chamber in darkness. It subsequently transpired that the transformer cellar had been entered by means of a false key and the connections severed. It is singular that similar extinctions of the light have previously occurred in different parts of Ireland. We remember a case at Carlow, when it was freely declared that the light had been tampered with; and it will be remembered that the light also suddenly went out in the Dublin Mansion House a short time back.

DUNDEE.—It has been decided by the Dundee Police Commissioners to remit the question of the lighting of the public clocks and of the central police office by electricity to a sub-committee for consideration.

EAST MOLESEY.—The Electric Lighting Committee have decided against Mr. Everett's proposed scheme of electric lighting, but they are willing to see the electric light adopted if found practicable, and are desirous of receiving other proposals on the subject.

ECCLES.—At a special meeting of the Town Council on Monday it was resolved "that application be made to the Board of Trade for a Provisional Order authorising the Council to purchase land, to construct works, and to produce, store, and sell electricity for lighting, motive, and other purposes."

EDINBURGH.—At the meeting of the Town Council on Tuesday a deputation of seven members was appointed to visit other towns, and to obtain information on the subject of electric lighting.

FALMOUTH.—The Town Council have under consideration the adoption of the electric light, and are making inquiries as to the cost.

GLASGOW.—It having been reported that a hitch had occurred in the electric lighting scheme for Glasgow, and that the original programme was likely to be departed from, Mr. W. Arnot, of the Corporation's gas and electric lighting department, writes to say that there is no truth in such rumours, but that the work is being carried out in accordance with the original plan.

HOLBORN, LONDON.—The Board of Works have agreed to a sum of £650 being expended in installing the electric light in the Holborn Town Hall.

LEYTON.—At the last meeting of the Local Board Messrs. Lorini and Bowman (Limited) stated that they had been requested to form a Company for lighting a portion of the main road of Leytonstone by electricity, and they wished to know if the Local Board would allow them any concession of the mains, and also they wished to know if they would take into consideration the advisability of lighting the remainder of the high road. Ultimately a motion to the effect that the Local Board make application to the Board of Trade to supply electric lighting to the district was carried.

NORTHAMPTON.—The increase in the demand for the electric light in this town has necessitated the laying down of additional plant, and the local company are issuing 5,000 Six per Cent. Cumulative Preference Shares of £1 each on easy terms, to enable them to purchase this plant in the best market. The consumption at the present time is 2¼ times what it was a year ago.

NOTTINGHAM.—In his report, which has now been adopted, to the Town Council on the electric lighting of the town, the engineer, Mr. H. Talbot, advises that the buildings at the generating station should be at first designed to contain sufficient plant for 13,000 8-c.p. lamps, but that plant should at first be only put down for 10,000 lamps. Boilers should be provided capable of supplying power for 20,000 lamps, and the types recommended are Galloway or Lancashire, with a feed water heater. With regard to engines, Mr. Talbot speaks highly of the Willans central valve engines, and the open type vertical engines made by Messrs. Davey, Paxman and Co., and Messrs. G. E. Belliss and Co. He advises that the dynamos should be tendered for by the best known makers, and that in the specification there should be clauses:—(1) Asking the contractor to state the amount of water he will guarantee shall not be exceeded per electrical horse power at dynamo terminals per hour. (2) The dynamos to be subject to an eight hours' continuous run at full load at the contractor's works in the presence of the Corporation's electrical engineer. (3) At the end of the run the selected dynamos to pass the Admiralty specification as regards heating, &c. Reference is made in the "Notes" to the discussion upon this and the Lighting Committee's report, which took place on Monday last.

REDRUTH.—The application of Messrs. Mitchell, Tangye and Tweedie for permission to light Redruth with electricity was approved by the Local Board at the last meeting.

SCARBOROUGH.—We are informed that the capital of the Scarborough Electric Supply Company (Limited), recently issued, has been allotted, and that work will commence at once. It is anticipated that the electric light will be supplied by June next. The alternate-current system has been adopted, with 1,000 volts pressure on the high-tension mains. Mr. A. A. Campbell-Swinton has been appointed the managing director of the Company.

SHEFFIELD.—The Highway and Sewerage Committee of the Town Council have given the usual notice that they intend to lay underground mains in certain streets of the town.

SUNDERLAND.—The Electric Lighting Committee have decided to recommend the Corporation to call in an expert to advise them as to the best course to pursue in reference to the electric lighting of the Borough, and as to the probable cost. In the meantime, the Borough Engineer has instructions to make all inquiries as to the probable demand for the light.

YORK.—The temporary arrangements for lighting the Law Courts at York have been completed, and have proved very satisfactory. The installation includes a Crossley gas engine and Crompton dynamo, and the electric lighting work has been carried on by Messrs. Benham and Sons (Limited), of London, under the supervision of Mr. W. Smith, that company's electrician.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

November 15, 1892.

20,606. C. A. DAY. London. Improvements in electric are lamps. (The Higham Electric Company, United States.)

20,610. G. L. ANDERS and W. KOTTGEN. London. Improvements in telephone circuits.

20,611. B. J. B. MILLS. London. Improvements in governing electric motors. (R. Lundell, United States.)

20,621. H. T. WILSON and N. SCHWAB. Manchester. Improvements in electric burglar alarms.

20,641. G. MURRAY. London. The carriage electric light apparatus.

20,665. P. RABBIDGE. London. An improved electro-magnetic alarm or call.

20,670. Sir C. S. FORBES, Bart. London. Improvements in the arrangement of telephone circuits and switching devices therefor.

20,693. F. HANSEN. London. Improvements in electric arc lamp.

20,698. H. H. BOYLE. London. An improved electric arc lamp.

20,700. D. JONES. London. Improved means for lighting trains by electricity.

COMPANIES' MEETINGS & REPORTS.

Electric Construction Corporation (Limited).

The following report of the Directors of this Company is to be submitted to the shareholders at the ordinary general meeting, to be held at Cannon-street Hotel, E C., this day (Friday), at 12 o'clock :—

Notwithstanding many unexpected difficulties which were encountered during the last twelve months, the result of the year's working shows a satisfactory balance to the credit of profit and loss account. The profit for the year is £46,693. 11s. 7d., after deducting the expenditure on plant, machinery, and patents, paying the interest on debentures and other loans, and placing a sum of £10,000 to a reserve for bad and doubtful debts. Including the balance of £10,721. 19s. 4d. from last year, there is a surplus to be dealt with of 57,415. 10s. 11d.

The amount of work executed during the last twelve months compares favourably with that of previous years. The contracts with the Liverpool Overhead Railway Company (Limited), and the South Staffordshire Tramways Company, have been nearly completed. The Liverpool overhead line is expected to be in full working order by the end of the year, and the Staffordshire Electric Tramway has already been passed by the Inspector of the Board of Trade, who has expressed himself thoroughly satisfied with the system employed and the work done by this Corporation. A very successful system has been carried out for lighting the City of Oxford, and the Directors have every reason to believe that these important works will serve to bring large additional contracts to the Corporation.

During the past year valuable experiments have been carried out at the laboratory of the Corporation at Bushbury, in connection with the present methods of producing zinc, chlorine, and alkalies. Mr. Parker cousiders the results which have been obtained highly encouraging, and a company has been formed for the purpose of commencing the manufacture on a commercial scale and to demonstrate the value of the patents.

Of the Preference Shares offered for subscription, 2,926 shares were taken up. The capital thus provided has not been sufficient for the purposes of the Corporation. With a view, therefore, to improve its general financial position, the Directors have consulted the Electric and General Investment Company (Limited). That Company has obtained a special report from the auditors, Messrs. Broads, Paterson, and Co., and has also caused an examination to be made of the works and plant at Wolverhampton by Messrs. Wheatley Kirk, Price, and Goulty, who have reported generally on the manufacturing business of the Corporation. As a result of obtaining these reports, and of their own investigation of the affairs of the Corporation, the Electric and General Investment Company (Limited) has agreed to issue £100,000 additional capital for the further development of the business, and has guaranteed that the subscriptions shall not be less than one-half of the issue ; such additional capital to be raised by the issue at par of Second Mortgage Debentures of £10 each, bearing interest at 6 per cent. per annum, and redeemable, at par, by half-yearly drawings over a period of about 15 years, and entitling the holder, by way of bonus, to an income bond of like amount, carrying interest as from the date of the redemption of the corresponding debenture at a rate for each year equal to the dividend declared on the ordinary shares for the preceding year. In order to secure for the shareholders the full benefit of this arrangement the Directors have stipulated with the Electric and General Investment Company (Limited) that the whole of the debentures shall be allotted to the shareholders in proportion to their respective holdings. All allotments not taken up by the shareholders or their nominees on or before the 19th inst. will be cancelled.

In accordance with the understanding arrived at with the Electric and General Investment Company (Limited), the Directors do not propose that any dividend be paid upon the ordinary shares for the past year, but they recommend that a dividend at the rate of 7 per cent. per annum be paid on the preference shares up to September 30th last ; that £30,000 be placed to a suspense account, and that the balance of £26,862. 1s. 5d. be carried forward.

Several retirements from the Board have taken place during the year, and as arranged with the Electric and General Investment Company (Limited), the Right Hon. David Plunket, Q.C., M.P., 12, Mandeville-place, W., and Mr. James W. Barclay, 5, Clarendon-place, Hyde Park, W., have been elected Directors, and will take their seats after the general meeting. The Directors who retire by rotation are Mr. James Pender and Mr. John B. Verity, who offer themselves for re-election. Messrs. Broads, Paterson and Co., the auditors, retire, but offer themselves for re-election.

The Directors are determined during the ensuing year to give their special attention to effecting economies in the expenses of administration, and they rely upon the next account showing material retrenchments in this respect, and that no occasions will arise for the exceptional expenditure shown in the accounts of the past year. They are confident also that the additional capital proposed to be raised for the purpose of developing the manufacturing business will be the means of largely increasing the net profits.

Elmore's Foreign and Colonial Patent Copper Depositing Company (Limited).

The following is the Directors' report to be presented at the annual meeting to be held at the Cannon-street Hotel on December 23rd, at 2 p.m. :—

The Directors have pleasure in submitting the balance-sheet and profit and loss account for the financial year of the Company ending December 31st last, showing a balance at that date of £132,203.

The year in question has been one of establishment and development of the French and German Elmore factories, which were started in the latter part of 1890 under the auspices of this Company, and the Directors are glad to be able to say that the Company working in France has now thoroughly proved the process on a large scale. The German Company, although they have had their difficulties, are now also making good progress, and will in the near future certainly make a success of their business. The Elmore manufactures are now admitted to be superior to anything else of the kind in competition with them, and this fact is being recognised by the highest authorities and the most exacting customers.

The recent report issued by the Directors of the French Company, in which this Company holds a very large interest, shows the comparatively low price of manufacture, whilst the steadily increasing output, and the fact that that Company is supplying a great number of consumers without any complaints from them, in several cases having received over 20 repeat orders, is the best proof of the success of the process on a large scale, and of the uniform quality of the products.

The Directors cannot at this time recommend the payment of a dividend, but they hope to be able, in the course of 1893, to make a distribution to the priority shareholders, leaving a handsome amount in hand for distribution among the founders. At the present moment, taking the Company's assets at par value, and after setting aside £5 per share and a fourth of the balance for the priority shares, or an extra £2. 15s. per share, there remains an amount equal to £13 per share for the founders.

The Company still hold a large number of patents for working the Elmore process in various foreign countries, the most important being Belgium, Italy, South America, India and the Colonies, and negotiations are on foot for the sale of some of the more valuable of these.

In accordance with the Articles of Association, one-third of the present Board of Directors retire from office. Upon this occasion Mr. F. L. Rawson retires, and being eligible, offers himself for re-election. Messrs. Jackson, Pixley, Browning, Husey and Co. offer themselves for re-election as auditors of the Company.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

ANDERSON, LAVERICK AND CO. (LIMITED).—This Company was registered on the 8th inst., with a capital of £10,000 in £5 shares, to acquire, take over as a going concern, and carry on the business of shipbuilders and repairers, iron and brass founders, mechanical and electrical engineers, toolmakers, metal workers, &c., carried on by Douglas M. Anderson and Stanley D. Laverick, at the Mushroom Slipway, St. Lawrence, Newcastle-upon-Tyne.
